**083554 ANALYSIS OF THE PRE-FOAMING AND INTERMEDIATE STORAGE STAGES IN EPS PROCESSING.** Because of their special properties, foamed plastics made from expandable polystyrene (EPS) have for a long time been successfully used for thermal insulation and as cushioning material in packaging. During processing of the raw material (polystyrene with incorporated blowing agent) into ready-to-use products, the process stages pre-foaming and intermediate storage impart to the material the specific properties of density and suitability for subsequent processing. The analysis of these process stages is intended to contribute to the realization of automated fabrication of moulded parts at the point of requirement of the products to be packaged. (Author abstract) 7 refs. In German and English.

**083555 CHLOROMETHYLATION OF POLYSTYRENES AND STYRENE COPOLYMERS. APPLICATIONS.** The authors study the chloromethylation of polystyrenes and their uses. It is shown that the partially chloromethylated polystyrenes are resistant to the flow of electrons (negative resists). This property is made use of in electronic lithography for microelectronics. This material gives good resolution, nearly of the order of a micron. Sensibility and resolution increase with increasing molecular weight but decrease with increasing polydispersity, which should be between 1.05 and 1.1 for the starting polystyrene. Chloromethylated polystyrenes are also utilized in soft X-ray resist. Chloromethylated polystyrene is also a starting polymer for visible light-sensitive recording material and UV lithography. 286 refs.

## Production

**083556 POLYSTYRENE (PS).** Demand for polystyrene in Western Europe has increased steadily since 1981 with an average growth rate of 3 to 4%. For 1987 the increase in demand will probably be 6 to 8% following a keen upturn in the tonnage produced. Over the medium term, annual growth is expected to be 1.5 to 2% on average. The product developments of West European polystyrene manufacturers over the past few years have focussed not so much on standard ranges but more on special-purpose products. These include products with flame retardant treatment, tough and stiff, high-gloss, impact-resistant polystyrenes and grades that are resistant to stress corrosion cracking. Added to these come more recent developments such as conductive, impact-resistant polystyrene, polystyrene/polyolefin blends and polystyrene-based sealable film. In the case of multilayer film with polystyrene as the carrier material, new combinations are constantly being developed for individual applications.

## Radiation Effects

**083557 CHAIN SCISSION OF POLYSTYRENE IN SOLUTION BY UV IRRADIATION AT HIGH TEMPERATURES.** Polystyrene dissolved in five different solvents such as benzene, cyclohexane, ethylbenzene, ethylcyclohexane, and decalin was irradiated by UV for eight hours in wide ranges of temperature from 20°C to their boiling points. Changes in the molecular weight, quantity of the carbonyl group formed, and gel contents as a result of irradiation were determined. The rate of main chain scission in all the solvents studied increases with increasing temperature until 100°C. It decreases with increasing temperatures above 100°C in ethylcyclohexane and decalin. The rate of chain scission depends on the quantity of the carbonyl group formed, and the main chain scission occurring via photooxidation. (Edited author abstract) 13 refs. In Japanese.

## Reaction Kinetics

**083558 KINETICS OF THE UNFOLDING OF COLLAPSED POLYSTYRENE CHAINS ABOVE THE GLASS TRANSITION TEMPERATURE.** Monodisperse polystyrenes with three molecular weights were doubly labeled with phenanthrene and anthracene and dissolved with a large excess of unlabeled polystyrene in benzene keeping the polymer concentration below the critical  $c^*$  value for chain overlap. After rapid freezing of the solution, the solvent was sublimed so that the individual chain molecules collapsed into compact globules. Pellets pressed from this material were heated above  $T_g$  and the expansion of the doubly labeled chains into the unlabeled matrix was monitored by the change in the emission spectrum due to a decreasing energy transfer from phenanthrene to anthracene with an increasing donor-acceptor separation. (Edited author abstract) 25 refs.

## Recovery

**083559 MODEL RECOVERY PROCESS FOR SCRAP POLYSTYRENE FOAM BY MEANS OF SOLVENT SYSTEMS.** A solvent technique is studied for the recovery of polystyrene (PS) foam waste. The model process proposed ensures removal of any impurities present and comprises dissolution of the starting material, filtering, reprecipitation, thorough washing of the polymer grains obtained and drying. The solvent mixtures involved are separated by distillation for re-use, the following criteria are considered: (a) the rheological behavior of the PS solutions prepared, (b) the yield of the process of polymer of acceptable grain size and (c) sufficient solvent/non-solvent separation. On the basis of these criteria, methyl ethyl ketone/n-hexane or methanol and p-xylene/n-heptane are suggested as effective solvent/non-solvent systems. (Author abstract) 11 refs.

## Research

**083560 HYDRODYNAMIC RADIUS OF POLYSTYRENE IN n-BUTYL CHLORIDE.** The authors study the translational diffusion coefficients which have been determined with the extended Taylor dispersion technique for a series of polystyrene standards with peak molecular weight  $M$  from 503 to  $10^6$  g/mol in cyclohexane at the  $\Theta$  temperature of 308 K and in n-butyl chloride (a good solvent) at temperatures from 278 to 348 K. The

hydrodynamic radii  $R_h$  calculated from the measured values of translational diffusion coefficients in n-butyl chloride will be compared with those in cyclohexane at  $\Theta$  temperature to examine possible solvent effects. From the comparison of  $R_h$  values in n-butyl chloride and cyclohexane, we conclude that the excluded volume effect on  $R_h$  expected of a good solvent is not observed for polystyrene chains with molecular weights up to  $10^6$ . Higher molecular weight is required for the coil expansion due to excluded volume perturbation to be observed. 15 refs.

Maa, Y.F. (Univ of Rochester, Rochester, NY, USA); Chen, S.H. *Macromolecules* v 21 n 4 Apr 1988 p 1176-1177.

**083561 EFFECT OF COMPLEXING AGENTS ON THE RATE OF POLYMERIZATION IN SYSTEMS INVOLVING DORMANT AGGREGATED POLYMERS AND LIVING NONAGGREGATED POLYMERS.** Lithium salts of polystyrene or polydienes are aggregated in hydrocarbon solvents. The aggregates are inert and the polymerization is carried out by a minute amount of unassociated polymers which are in equilibrium with the aggregates. Various solvating agents may dissociate the aggregates by being complexed with the unassociated polymers. The resulting complexes have usually a 1:1 stoichiometry and contribute to propagation; however, their rate of growth is, on the whole, different from that of the unassociated polymers. It is found that initial addition of a complexing agent to a dimerically aggregated lithium polystyrene, or to another similarly aggregated living polymer, increases the rate of polymerization when the total concentration of polymers, in all its forms, exceeds  $(k_p/k_c) 2K_{diss}/8$  and decreases it when the inequality is reversed. 3 refs.

**083562 FORCES BETWEEN SURFACES BEARING TERMINALLY-ANCHORED POLYMER CHAINS.** The forces have been measured between mica surfaces bearing terminally-anchored, non-adsorbing polymer chains in good solvents. In the first case PS was end-functionalized with a zwitterionic group. In the second case a block copolymer was used, containing a small number of polyethylene oxide monomers. Excellent quantitative agreement was found between the experimental results and the theoretical prediction for all molecular weights. This suggests that the scaling approach may indeed be a valuable tool in understanding the interactions between layers of terminally-anchored polymer chains in good solvent conditions. 7 refs.

## Separation

**083563 PHASE SEPARATION OF OLIGOMERIC POLYSTYRENE-POLYBUTADIENE BLENDS AS STUDIED BY EXCIMER FLUORESCENCE.** The binodal curve and phase separation behavior of 826 MW polystyrene (PS)/2500 MW polybutadiene (PB) blends have been studied by optical density measurements and fluorescence spectroscopy, respectively. The equilibrium compositions from the binodal curve and the Gelles-Frank two-phase model, which relates the composition of phases generated during spinodal decomposition to the ratio of excimer to monomer fluorescence intensity,  $I_E/I_M$ , were used to follow the time-dependent compositions of the phases during phase separations as well as the kinetics of phase separation. For 30 wt% and 60 wt% PS blends quenched at 32°C, the change in  $I_E/I_M$  during phase separations was quite small, less than 10%, but nevertheless large enough to yield precise information. (Edited author abstract) 38 refs.

**083565 RELATIONSHIP OF INTRINSIC VISCOSITY OF POLYMER SOLUTIONS TO MOLECULAR WEIGHT.** An equation derived by C.C. Han relating intrinsic viscosity to molecular weight of a polymer has been fitted to experimental data over a range of molecular weight. Excellent fits were obtained although the Mark-Houwink equation did not fit the data over the complete molecular weight range. C.C. Han's equation may be fit to intrinsic viscosity data over a moderate range of molecular weight, and is shown to then accurately predict the intrinsic viscosities for molecular weights outside this range. A method is given to compute the two parameters of this equation from the Mark-Houwink parameters of a polymer in a solvent. (Edited author abstract) 13 refs.

**083566 LIGHT SCATTERING FOR POLYSTYRENE SOLUTIONS IN CYCLOPENTANE NEAR THE UPPER AND LOWER CRITICAL SOLUTION POINTS.** Thermostats were constructed for light scattering at high temperatures up to 200°C. The intensity and line width of scattered light were measured for polystyrene solutions in cyclopentane near the lower critical solution point. The measurements for the same system near the upper critical solution point were performed for comparison. The values of critical exponents  $\gamma$  and  $\nu$  were found to be  $\gamma_U = 1.16$  and  $\gamma_L = 0.59$  for the upper side, and  $\gamma_L = 1.15$  and  $\nu_L = 0.58$  for the lower side. The dependences of line width on the temperature and wave number on the lower side were almost the same as those on the upper side. (Edited author abstract). In Japanese. 19 refs.

**083567 QUANTITATIVE MODEL FOR THE FORMATION OF ADSORPTION-ENTANGLEMENT LAYERS.** The formation of thick adsorption-entanglement layers at foreign surfaces during the flow of high molecular weight polymer solutions is now well documented. This paper presents a quantitative model which describes the formation of such layers in terms of the polymer molecular weight and radius of gyration, the solution concentration and the local flow velocity. The model is tested against experiments using capillary flow and atactic polystyrene solutions. The agreement between theory and experiment is very good. (Author abstract) 5 refs.

**083568 MONTE CARLO CALCULATIONS IN**

**COMPARISON TO NEUTRON SCATTERING STUDIES: 2. GLOBAL DIMENSIONS OF 12-ARM STARS.** Light and neutron scattering studies were carried out on 12-arm star polystyrene molecules in toluene (a good solvent) and in cyclohexane (a  $\theta$ -solvent). The polymers had a molecular weight range of  $5 \times 10^4 < M_w < 1.6 \times 10^6$ . The global dimensions of all samples under  $\theta$  conditions are larger than those predicted by the existing theories. Monte Carlo simulations of 12-arm star chains as a function of chain length were performed using Flory's rotational isomeric state model. Two different types of star chains, a pure combinatorial star and a star with a specific centre were used. These aided the interpretation of the experimental results. (Author abstract) 33 refs.

Huber, Klaus (Univ of Freiburg, Freiburg, West Ger); Burchard, Walther; Bantle, Siegfried; Fetters, Lewis J. *Polymer* v 28 n 12 Nov 1987 p 1990-1996.

**083569 MONTE CARLO CALCULATIONS IN COMPARISON TO NEUTRON SCATTERING STUDIES: 3. ON THE STRUCTURE OF 12-ARM STAR MOLECULES.** The small-angle neutron scattering curves of polystyrene 12-arm star molecules exhibit deviations from the Gaussian star model according to Benoit. These deviations are comparable with those observed in the scattering curves of simulated polymethylene 12-arm star chains. They can be partially interpreted in terms of chain stiffness within the arms. If the simulated chains contain a specific star centre, their scattering curves, normalized by the radius of gyration, are in good agreement with the normalized experimental scattering curves. For very short arms the scattering curves of the simulated chains with a specific star centre approach the particle scattering factor of the rod-like star model. (Author abstract) 13 refs.

**083570 HIGH-PRESSURE SOLUTION BEHAVIOR OF THE POLYSTYRENE-TOLUENE-ETHANE SYSTEM.** The effect of supercritical ethane on the high-pressure phase behavior of the polystyrene-toluene system is experimentally investigated. Adding 17.8 wt.% ethane to the polystyrene-toluene solution lowers the temperature of the lower critical solution temperature (LCST) curve by 162°C, 22.5 wt.% lowers the temperature of the curve by 231°C, and with 24.9 wt.% the curve is shifted to such low temperatures that it merges with the upper critical solution temperature curve. In practice this means that polymer solutions can be separated at lower temperatures where thermal degradation of the polymer is less. (Edited author abstract) 28 refs.

**083573 DETERMINATION OF STEREOCHEMICAL COMPOSITIONS OF OLIGOSTYRENES BY <sup>13</sup>C NMR.** Solution properties such as the mean-square radius of gyration and the mean-square optical anisotropy are affected by the stereochemical composition (expressed by the fraction  $P_r$  of racemic dyads) of atactic  $\alpha$ -hydro- $\omega$ -butylpolystyrenes. In order to determine  $P_r$ , we need the assignments of <sup>13</sup>C NMR spectra of the samples. In this report, we make assignments of spectra of the pentamer with the help of calculated chemical shifts obtained by taking quantitative account of the  $\gamma$  effect on the basis of the rotational isomeric state (RIS) model. The adequacy of the calculated values is verified for the case of the tetramer for which the assignments were made. With these assignments,  $P_r$  of the tetramer and pentamer are determined from measured <sup>13</sup>C NMR spectra of these samples. 11 refs.

**083574 KINETICS OF ION-PAIR INTERCHANGE IN IONOMER SOLUTION.** Solutions of polystyrene in which 3.4 and 6.9 mol% of the monomer residues were sulfonated were partially neutralized with 2-(aminomethyl)naphthalene and 9-(aminomethyl)anthracene, respectively. The solutions were mixed in a stopped-flow apparatus and the interchange of the two counterions was followed by the increase in the anthracene emission intensity, when the solution was irradiated in the naphthalene absorption band, due to an increasing efficiency of nonradiative energy transfer. The kinetics of the process were studied as a function of the polymer concentration in dioxane and a 1:1 mixture of dioxane and cyclohexane, as a function of the excess of unneutralized sulfonic acid groups, and as a function of temperature. (Author abstract) 13 refs.

**083575 DIELECTRIC CONSTANT NEAR THE LIQUID-LIQUID CRITICAL POINT FOR POLYSTYRENE IN DIETHYL MALONATE.** We have measured the dielectric constant as a function of temperature and frequency near the liquid-liquid critical point of a mixture of polystyrene (molecular weight  $1.02 \times 10^5$ ) in diethyl malonate at the critical composition. The range of the frequency was 20 kHz to 1 MHz. For the one-phase region above the critical point, the range of the temperature was  $1.1 \times 10^{-5} < t < 7.9 \times 10^{-2}$ . The dielectric constant in the one-phase region near the critical point shows an anomalous increase of about 0.3% above the 'background' behavior far from the critical point. (Edited author abstract) 53 refs.

**083576 MOLECULAR INTERACTIONS IN POLYSTYRENE COSOLVENT SYSTEMS.** Studied are miscible binary cosolvents for polystyrene, for which polystyrene is insoluble in either of the individual solvents. Polymer-solvent interactions in solutions of atactic polystyrene in acetone/diethyl ether and in methylcyclopentane (MCP)/acetone binary cosolvents have been investigated using nuclear magnetic resonance (NMR) spectroscopy. Polystyrene <sup>13</sup>C chemical shifts were measured as a function of miscible binary solvent compositions and temperature. The NMR data were used to calculate 'association constants' as a measure of specific interac-

tions of the solvent components with all sites on the polymer. In mixtures of acetone and diethyl ether, <sup>13</sup>C-NMR indicates a weak interaction between the polystyrene phenyl ring and the diethylether solvent component. In the polystyrene/MCP/acetone system, present NMR data reveal no preferential interactions. Additional NMR measurements were performed on polystyrene in mixtures of CCl<sub>4</sub>/acetone. From these results, it is concluded that although preferential polymer-solvent interactions are present in some cosolvent systems, they are not a prerequisite for such behavior. (Author abstract) 13 refs.

**083577 DILUTE SOLUTION BEHAVIOR OF ASYMMETRIC THREE-ARM AND REGULAR THREE- AND TWELVE-ARM POLYSTYRENE STARS.** The dilute solution characteristics of regular three- and twelve-arm and asymmetric three-arm polystyrene stars have been studied under  $\Theta$  conditions (cyclohexane) and in a good solvent (toluene). The parameters evaluated include the intrinsic viscosities and for the regular stars the radii of gyration and the viscometric based radii. The twelve-arm stars show the influence of high segment densities near the star core under  $\Theta$  conditions; i.e.,  $g_{\Theta}$  decreases as arm molecular weight increases and approaches the random-walk prediction only at high-arm molecular weight. Additional parameters describing the regular and asymmetric star-shaped polymers are presented and discussed. (Author abstract) 72 refs.

Khasat, Nitya (Univ of Akron, Akron, OH, USA); Pennisi, Robert W.; Hadjichristidis, Nikos; Fetters, Lewis J. *Macromolecules v 21 n 4 Apr 1988 p 1100-1106.*

**083578 LIGHT SCATTERING STUDY OF IONOMERS IN SOLUTION. 2. LOW-ANGLE SCATTERING FROM SULFONATED POLYSTYRENE IONOMERS.** Low-angle light scattering studies were conducted for partially sulfonated polystyrene ionomers in a polar and a low-polarity solvent. In the low-polarity solvent tetrahydrofuran (THF), aggregation of ionomers due to the attraction of ion pairs was seen in changes of molecular weight and interaction parameter (second virial coefficient) with ion content. At high ion content, negative interaction parameters were observed. In the polar solvent dimethylformamide (DMF), typical polyelectrolyte behavior was observed in light scattering data. Effective diameters of macroions (ionomers) were used to discuss the effect of counterion and ion content on the structural change of ionomers. (Author abstract) 40 refs.

**083579 COMPARISON OF CORRELATION LENGTHS IN SEMIDILUTE POLYSTYRENE SOLUTIONS IN GOOD SOLVENTS BY QUASI-ELASTIC LIGHT SCATTERING AND SMALL-ANGLE NEUTRON SCATTERING.** Quasi-elastic light scattering (QELS) and small-angle neutron scattering (SANS) experiments have been made on semidilute solutions of polystyrene (PS) in methylene chloride and tetrahydrofuran. The hydrodynamic screening length ( $\zeta_H$ ) from QELS and the excluded volume screening length ( $\zeta$ ) from SANS are found to be proportional at concentrations well above the dilute-semidilute crossover. The power law  $C^{-0.68}$  applies to the static quantity whereas this asymptotic exponent value is only found for  $\zeta_H$  with PS fractions of molecular weight  $M \geq 10^6$ . The dynamic length,  $\zeta_H$ , is solvent independent while the static length is shown to be significantly shorter in methylene chloride, a result which is possibly related to differing extents of coil interpenetration in these solvents. (Edited author abstract) 37 refs.

**083580 SMALL-ANGLE X-RAY SCATTERING FROM SEMIDILUTE POLYMER SOLUTIONS. DEUTERATED POLYSTYRENE-DEUTERATED**

**CYCLOHEXANE SYSTEM.** Binary ( $B_1$ ) and ternary ( $B_2$ ) cluster integrals of deuterated polystyrene in deuterated cyclohexane were determined by small-angle X-ray scattering from semidilute solutions. The results were compared with those previously determined for the undeuterated polystyrene-deuterated cyclohexane system and undeuterated polystyrene-undeuterated cyclohexane system. It was found that for all cases  $B_2$  was unaltered by deuterium substitution within the experimental accuracy and had the value  $0.8 \times 10^{-51} \text{ cm}^6$  almost independently of temperature, whereas  $B_1$  had the temperature dependence of the form  $B_1 = B_{10}(1 - \theta/T)$  near the  $\theta$  temperature, where temperature independent factor  $B_{10}$  was also unaffected by deuteration; the sole deuteration effect observed was a shift of  $\theta$  temperature at which  $B_1$  vanishes. (Author abstract) 10 refs.

**083581 POLYMER SCIENCE SELF-DIFFUSION OF POLYSTYRENE IN SOLUTION: 1. EXPERIMENTAL RESULTS OF THE NMR PULSED FIELD GRADIENT TECHNIQUE.** We report self-diffusion measurements for polystyrene dissolved in benzene and chloroform using the NMR pulsed field gradient technique. The observed echo attenuations point to dynamic exchange processes or cluster formation in the semidilute solution. The experimental results are compared with theoretical predictions from the reptation mechanism and the 'blob' theory. There is qualitative agreement, but a more comprehensive analysis of the data and results from experiments with polymer mixtures show that polymer self diffusion in semidilute solutions cannot be explained by the reptation mechanism in its simple form. (Author abstract) 28 refs.

Fleischer, G. (Karl-Marx-Univ Leipzig, Leipzig, East Germany); Zgadzai, O.E.; Skirda, V.D.; Maklakov, A.I. *Colloid Polym Sci v 266 n 3 Mar 1988 p 201-207.*

**083582 SELF-DIFFUSION OF POLYSTYRENE IN SOLUTION: 2. DISCUSSION OF EXPERIMENTAL RESULTS ON THE BASIS OF THE REPTATION MECHANISM AND ENTANGLEMENTS.** The expressions for polymer self-diffusion in semidilute solutions, theoretically derived from the reptation mechanism, the blob concept and scaling considerations, are discussed and compared against experimental data. In the nontangled (from viscoelastic data) semidilute solution, the experimentally observed concentration and molar mass exponents are in fair agreement with those derived theoretically. However, a quantitative estimation shows that the experiments cannot be explained by reptation. Experiments with polymer mixtures also give strong evidence against reptation. It is concluded, that in the nontangled semidilute solution, the polymer self-diffusion is more complicated than simple reptation. This is also supported by recently observed long-range density fluctuations or cluster formation in this concentration region. In the entangled semidilute solution, the self-diffusion data are in accordance with the reptation mechanism. (Edited author abstract) 42 refs.

Fleischer, G. (Karl-Marx-Univ Leipzig, Leipzig, East Germany); Zgadzai, O.E. *Colloid Polym Sci v 266 n 3 Mar 1988 p 208-215.*

**083583 DISTRIBUTION OF RELAXATION TIMES FROM DYNAMIC LIGHT SCATTERING ON SEMIDILUTE SOLUTIONS: POLYSTYRENE IN ETHYL ACETATE AS A FUNCTION OF TEMPERATURE FROM GOOD TO  $\Theta$  CONDITIONS.** Intensity correlation functions have been measured over widely spaced delay times, covering 6-8 decades, for polystyrene in semidilute solutions of ethyl acetate. The solvent quality was changed systematically by varying the temperature from +70 (moderately good) to -44°C ( $\Theta$  conditions). Measurements were performed as a function of both angle and concentration. Distributions of relaxation times were extracted from the correlation functions by inverse Laplace transformation. Three relaxational modes are established in the decay time spectrum. The fast

mode corresponds to network dynamics ( $K^2$  dependent), while the following tentative assignments of the slower modes are made: (a) middle mode, insufficiently resolved for characterization, possibly contaminated by another dynamical process; (b) slow mode ( $K^2$  dependent), characterizes the concentration fluctuations associated with the motions of clusters of chains. (Edited author abstract) 52 refs.

**083585 STRESS RELAXATION OF SEMIDILUTE POLYSTYRENE SOLUTIONS. A NEW OBSERVATION WITH  $\Theta$ -SOLVENT AND WITH BLENDS CONTAINING VERY SHORT CHAINS.** The authors investigated the effects of very short chains. They also performed measurements on a solution of polystyrene of high molecular weight in a  $\theta$ -solvent since the authors expected that the deviation might be caused by an enhanced concentration fluctuation of the high  $M$  component. It is shown that the results for the monodisperse and bimodal systems in DOP (diethylhexyl phthalate) solvent agree with each other. The short chain component does not affect the shape of curve in the terminal region. In summary, weakening of the solvent power or the contamination with very short chains makes the relaxation spectrum range diffuse. 3 Refs.

**083586 TEMPERATURE DEPENDENCE OF THE INTRINSIC VISCOSITY OF SOLUTIONS OF POLYSTYRENE AND POLYALKYLSTYRENES.** The experimental findings on the temperature dependence of intrinsic viscosity of solutions of PS and polyalkylstyrenes treated by the modified Flory equation gave values of the entropic parameter  $\psi_1$  concurring with the magnitudes  $\psi_1$  obtained from the molecular-mass dependence of the critical temperature of mixing. The excluded volume of the macromolecules of the polyalkylstyrenes insignificantly exceeds that for PS pointing to the closeness of their transverse dimensions, i.e. the low rigidity of the side chains of the polyalkylstyrenes. (Author abstract) 16 Refs.

## Sorption

**083587 EFFECT OF ORIENTATION ON THE CO<sub>2</sub> SORPTION OF POLYSTYRENE.** The chain orientation, induced by hot drawing, decreases the sorption capacity of polystyrene due to the tighter packing of macromolecules in the oriented material. Density measurements and decay of birefringence indicate that the loss of orientation is a much more rapid phenomenon than the thermal shrinkage of the polymer. (Author abstract) 13 refs.

## Specific Heat

**083588 KINETICS OF ENTHALPY RELAXATION IN GLASS TRANSITION OF FLEXIBLE-CHAIN POLYMERS.** Heat capacity has been measured between 308 and 523 K for a number of polymers: four narrow-distribution polystyrene fractions and a non-fractionated polystyrene sample; statistical copolymers of styrene with methyl methacrylate and styrene with acrylonitrile; polycarbonate and polysulfone. The samples were first cooled from the melt at different rates. Parameters in the Moynihan model of enthalpy relaxation accompanying the glass transition were determined for the studied polymers. Empirical correlations were established between a phenomenological parameter characterizing the width of spectrum of relaxation times and the polymer molecular weight and, on the other hand, the dimensionless ratio  $\Delta E/RT_g$ . (Author abstract) 20 refs.

**083589 DETERMINATION OF BIMODAL MOLAR MASS DISTRIBUTION FUNCTIONS OF POLYSTYRENE BY PHOTON CORRELATION SPECTROSCOPY: NUMERICAL SIMULATIONS AND EXPERIMENTAL REALIZATION IN COMPARISON WITH GEL PERMEATION CHROMATOGRAPHY DATA.** The resolution of bimodal molar mass distribution functions of polymers by photon correlation spectroscopy (PCS) combined with the constrained regularization method and the estimation of the noise level of PCS measurements is presented. Molar mass distribution functions have been recalculated from the simulated autocorrelation functions. Simulation outputs show an increase of the polydispersity and a shift toward smaller molar masses with increasing statistical noise. The effective noise level of the present measurements was determined. (Edited author abstract) 25 refs.

**083590 PHOTON CORRELATION SPECTROSCOPY FROM DILUTE POLYMER-POLYMER MIXTURES.** The authors examine the molecular weight, concentration, and temperature dependences of the initial decay of the light-scattering photon correlation from dilute mixtures of low molecular weight polystyrenes in poly(methylphenylsiloxane). The authors observe the  $q^2$  dependence previously reported from these mixtures. For polystyrene molecular weights substantially larger than that of the poly(methylphenylsiloxane) macromolecules, the infinite dilution limit of the diffusion coefficient extracted from the initial decay follows a molecular weight dependence close to  $M^{-0.5}$ . For the very dilute mixtures studied, the variation of the diffusion coefficient with concentration appears to be independent of temperature. The temperature dependence of the initial decay rate of the correlation deviates from an Arrhenius behavior as the coexistence curve of the mixture is approached. (Author abstract) 8 refs.

**Structure** See Also POLYBUTADIENES—Structure.

**083593 CHANGES OF THE STRUCTURE AND PROPERTIES OF POLYSTYRENE UNDER THE INFLUENCE OF COMPLEX ACTIVATION.** In this communication the authors report data on the structure and properties of polystyrene (PST) obtained in an aqueous solution of the cationic emulsifier cetylpyridinium chloride (CPC) at room temperature under the influence of radicals produced by decomposition of the CPC-benzoyl peroxide complex. The aim of these investigations was to solve certain practical problems in relation to possible modification of the polymer under conditions of donor-acceptor interaction of components of the reaction medium. It was found that PST<sub>0</sub> has higher thermal stability than PST<sub>c</sub>; when PST<sub>0</sub> is heated for 3 h at 300 and 350°C the weight loss is 5 and 15% respectively, while in the case of PST<sub>c</sub> the corresponding losses are 15 and 45%. The authors consider on the basis of their results that the formation of nonshrinking and thermostable polystyrene under conditions of complex activation, with good dielectric properties without orientation stretching, may be regarded as a possible method of modifying polystyrene in order to extend the regions of its application as an insulating material. 4 refs.

**083594 ANISOTROPIC STRUCTURE FORMED IN ATACTIC POLYSTYRENE GELS.** In order to elucidate the mode of gelation and the structure of the gels, we investigated the morphology and properties of at-Pst/CS<sub>2</sub> gels. In the course of study, it was found that not a small number of patches with an anisotropic structure are formed in the uniform gel matrix. This anisotropic patches disappear when the gel melts on heating, but survive in the dried gel. However, this anisotropic patches never appear in the solvent-cast films, indicating that the gelation is necessary for their origination. 10 refs.

**083595 LIGHT-INDUCED SPECTRAL CHANGES IN ROSE BENGAL END-CAPPED POLYSTYRENE.** Light-induced changes in the absorption spectra of Rose Bengal end-capped polystyrenes in nonpolar solvents have been observed. The spectra of the Rose Bengal polymers obtained after irradiation are clearly indicative of the photochemical conversion of Rose Bengal monomer to Rose Bengal aggregate in the nonpolar solvent. The results suggest that a photochemically induced polymer backbone conformational change driven by intramolecular dye-dye aggregation is giving rise to the observation. (Author abstract) 8 refs.

**083596 PHASE CONTRAST MATCHING IN LAMELLAR STRUCTURES COMPOSED OF MIXTURES OF LABELED AND UNLABELED BLOCK COPOLYMER FOR SMALL-ANGLE NEUTRON SCATTERING.** To extract the single-chain scattering function of polystyrene block chain in lamellar structures of styrene-2-vinylpyridine diblock copolymers, the method of 'phase contrast matching' was studied for small-angle neutron scattering from blends of the deuterium-labeled and unlabeled block copolymers. The phase contrast matching is successfully applied for the samples with the lowest molecular weights ( $3.4 \times 10^4$  for the labeled portions) but not for the samples with the higher molecular weights ( $9.2$  and  $16.2 \times 10^4$ ). It is concluded that the mismatching may be caused by concentration fluctuation in the mixture of hydrogenated and deuterated polystyrenes in domains, as well as by nonuniform distribution of deuterated species along the direction perpendicular to the lamellae due to the difference in lengths of the labeled and unlabeled blocks. (Author abstract) 24 refs.

## Structures

**083597 NEW METHOD FOR QUANTITATIVE FUNCTIONALIZATION OF THE TERMINUS IN POLY(STYRENE), NAPHTHALENE FUNCTIONALIZATION.** The authors report a general functionalization method to prepare polymers labeled with fluorescent groups based on the addition reactions of polymeric carbanions to diphenylethylene derivatives. An efficient coupling reaction to synthesize polymers labeled with fluorescent aromatic groups for the functionalization of poly(styryl)lithium (PSLi) with a naphthalene (N) derivative to yield an end-labeled poly(styrene) (PS-N) is used. The number-average molecular weight and molecular weight distribution of the naphthalene end-labeled polystyrene were characterized by size-exclusion chromatography. These results show that there has been no major change either in  $M_n$  or  $M_w/M_n$ . 18 Refs.

## Surface Properties

**083598 SORPTION PROPERTIES OF POLYSTYRENE ADSORBENTS FROM ISOTHERMS OF PROPANE AND n-BUTANE.** Adsorption isotherms for propane and n-butane on two polystyrene samples of high and low specific surface areas were obtained from measurements of transmission or breakthrough curves. These isotherms were analyzed to extract the parameters that characterize the energetic heterogeneity of polystyrene. The energetic heterogeneity of the sample with low specific surface area reflects only the surface heterogeneity of polystyrene; therefore, this sample was used as a reference system to study the polystyrene sample with a high specific surface area. Analysis of the adsorption isotherm suggests that the sample with a high specific surface area possesses micropores that increase its energetic heterogeneity in comparison to that observed for the sample with low specific surface area. (Author abstract) 12 refs.

**083599 SURFACE COMPOSITION OF POLYSTYRENE.** The physical and chemical properties of bulk polymers are well understood and have been measured

exhaustively for numerous systems, but the properties of polymer surfaces are quite often different from those observed in the bulk and are usually not as easily measurable. Since many polymer properties vary with molecular weight, it is of interest to determine whether or not there is any segregation in a homopolymer system based on molecular weight. In particular, does the surface of a polymer sample have the same molecular weight composition as the bulk? The current work answers this question for a polystyrene system. Through the use of secondary ion mass spectrometry and tagged polystyrene, it has been shown that surface and bulk molecular weight composition are indistinguishable within the limits of the experimental method's sensitivity. **083602 ANOMALOUS PENETRANT TRANSPORT IN GLASSY POLYMERS - VI. EFFECT OF TEMPERATURE ON TRANSPORT.** Transport of liquid cyclohexane through well characterized, initially glassy, crosslinked polystyrene slabs was investigated at 20, 30, 40, and 50°C. The samples used were produced by bulk polymerization of styrene and divinyl benzene (DVB) at 90°C for 48 hr using benzoyl peroxide as an initiator. Cyclohexane uptake was followed as a function of time along with dimensional changes in the thickness and area of the samples. The results of penetrant uptake as a function of time were analyzed using a simplified exponential expression and employing all the data points from the beginning of the experiment until the time of observation of the maximum in uptake. (Edited author abstract) 29 refs.

**Synthesis**

**083603 RADICAL COPOLYMERIZATION OF SULPHUR DIOXIDE AND STYRENE: 4. INTRAMOLECULAR EXCIMER FORMATION IN POLY(STYRENE SULPHONE).** Intramolecular excimer formation in poly(styrene sulphone) with various compositions has been investigated on the basis of the characteristic monomer sequence distributions which were determined experimentally. The fluorescence spectra of the poly(styrene sulphone)s show two emission bands at 285 nm and 330 nm for polystyrene, corresponding to the monomer and the excimer bands, respectively. The ratio of the excimer to the monomer emission intensities ( $I_e/I_m$ ) is linearly correlated with the mole fraction of styrene. This observation is consequence of the characteristic sequence distributions in poly(styrene sulphone)s, containing a very small fraction of SMS units ( $S=SO_2$ ;  $M=$  styrene). The efficiency of excimer formation in poly(styrene sulphone)s with regular styrene sequences, e.g.  $I_e/I_m$ . It is concluded that the excimer formation in poly(styrene sulphone)s is very efficient. (Edited author abstract) 27 refs.

**Thermal Conductivity**

**083606 LOW TEMPERATURE THERMAL CONDUCTIVITY OF POLYSTYRENE.** The thermal conductivity  $\kappa$  of amorphous polystyrene has been measured in the temperature range 0.1 K-100 K as a function of molecular weight, cross-linking and annealing. We find  $\kappa$  insensitive to sample preparation and the number of type of chain ends. Crosslinking increases  $\kappa$  predominantly in the temperature range of the plateau. Our results suggest an inverse relationship between the fictive temperature and the thermal conductivity measured at temperatures below 1 K. (Author abstract) 40 refs.

Mack, J.X. (Univ of Illinois at Urbana-Champaign, Urbana, IL, USA); Freeman, J.J.; Anderson, A.C.; Greig, D. *J Non Cryst Solids* v 91 n 3 Jun 1 1987 p 391-401.

**Thermal Effects**

**083607 THERMAL STABILITY OF BENZOYL PEROXIDE INITIATED POLYSTYRENE.** In various studies the authors prepared polystyrene with  $^{13}C$ -labeled end groups by conducting polymerizations with benzoyl-carbonyl- $^{13}C$  peroxide as the initiator. These polymers were used to assess the thermal stability of the benzoyloxy end groups present in benzoyl peroxide initiated polystyrene and to ascertain whether they constitute 'weak links' in polystyrene. Examination of the NMR spectra of the degraded polymers showed that after only 10 min all resonances due to secondary benzoate end groups have disappeared while the primary benzoate resonances appear essentially unchanged both in appearance and relative intensity. 15 refs.

**083608 MONOLAYER OF POLYSTYRENE MONOMOLECULAR PARTICLES ON A WATER SURFACE STUDIED BY LANGMUIR-TYPE FILM BALANCE AND TRANSMISSION ELECTRON MICROSCOPY.** The behavior of a monolayer of polystyrene monomolecular particles which was obtained by spreading dilute solutions in benzene on the water surface was studied by a Langmuir-type film balance and transmission electron microscopy (TEM). Since polystyrene has no hydrophilic group, the surface pressure measured by the film balance was not due to the real decrease of the surface tension but due to a mechanical force by compression, thus the  $\pi$ -A curves were apparent  $\pi$ -A curves. However, the macroscopic observation by the film balance was in good agreement with the microscopic observation by TEM, indicating the particles are stable against the compression. At the limiting area,  $A_0$ , the monomolecular particles covered 56% of the water surface, but they could not be most closely packed by further compression. Apparent  $\pi$ -A curves were measured for lower molecular weight samples, for which formation of monomolecular particles has not been confirmed. The observed small  $A_0$  indicated the particles were not formed or were unstable against the compression. (Edited author abstract) 13 refs.

**083609 POLYMERIZATION IN SUBMONOLAYERS OF STYRENE MONOMER ADSORBED FROM ITS VAPOR PHASE.** The surface coverage of porous glass ( $PD = 500$ ) by styrene adsorbed from its vapor (0.1-6 torr) was studied in a vacuum electrobalance. The adsorption isotherm of the monomer was analyzed by the BET method, and a full monolayer coverage was found to form at a relative pressure of 0.11, weighing 6 mg per gram of glass. Polymerization in submonolayers of adsorbed styrene was initiated by thermal decomposition of predeposited BPO and found to continue until all initiator decomposed, sample cooled, or vapor removed, hence allowing a controlled film thickness. The films were extracted in THF and analyzed by computerized GPC. Molecular weights were in the range 18000-69000. These were related to the rates of polymerization by the usual statistical correlations. (Author abstract) 10 Refs.

**Viscoelasticity**

**083610 VISCOELASTIC PROPERTIES OF AQUEOUS CONCENTRATED POLYSTYRENE LATEX**

**DISPERSIONS CONTAINING GRAFTED POLY(ETHYLENE OXIDE) CHAINS.** The viscoelastic properties of aqueous concentrated polystyrene latex dispersions containing grafted poly(ethylene oxide) (PEO) chains were investigated using oscillatory and steady-state shear stress-shear rate measurements. The relative viscosity-effective volume fraction results were fitted to the Dougherty-Krieger equation for hard spheres by adjusting the value for the adsorbed layer thickness  $\Delta$ . The latter was found to decrease with an increase in volume fraction of the dispersion and near to close-packing considerable compression of the chains occurred. The results showed that the dispersion changes from being more viscous to more elastic over a narrow range of volume fraction  $\phi$  of the dispersion, i.e., when  $\phi$  is increased from 0.465 to 0.5. (Author abstract). 6 Refs.

## Viscosity

**083611 COUNTERION AND SOLVENT EFFECTS ON THE DILUTE SOLUTION VISCOSITY OF POLYSTYRENE IONOMERS.** We present an analysis of data on the intrinsic viscosity  $[\eta]$  of sulfo-polystyrene ionomers in several solvents for a variety of sulfonation levels and counterions. For solvents of low dielectric constant,  $2 < \epsilon < 18$ ,  $[\eta]$  decreases from the base polymer value  $[\mu]_0$  with increasing substitution level. This behavior was attributed to intramolecular association of ionic dipoles. The ratio  $[\eta]/[\eta]_0$  was found to depend on a single reduced variable  $a_A a_{Sx}$ , where  $x$  is the fractional substitution,  $a_A$  depends only on the counterion, and  $a_S \propto \epsilon^{-1}$  depends only on the solvent. For solvents of high dielectric constant,  $36 < \epsilon < 47$ ,  $[\eta]$  increases approximately as  $x^3$ , and counterion effects are small. (Edited author abstract) 23 refs.

Agarwal, Pawan K. (Exxon Research & Engineering Co, Annandale, NJ, USA); Garner, Richard T.; Graessley, William W. *J Polym Sci Part B* v 25 n 10 Oct 1987 p 2095-2111.

## Waste Utilization

**083612 MODEL PROCESS FOR THE SOLVENT RECYCLING OF POLYSTYRENE.** A model solvent technique is presented according to which polystyrene (PS) foam scrap is recovered in the form of small grains. The process mainly comprises dissolution of the waste into benzene or toluene, filtering, dispersion of the solution into water, and subsequent distillation. The alternative solvent/non-solvent systems have been studied on the basis of solution rheology, operating conditions during the recycling procedure, and extents of recovery of PS and solvent. Eventually, the toluene/water system has been chosen for a larger scale experiment (LSE), the product of which was used for characterization work. No influence on critical properties was detected due to the solvent technique followed. (Author abstract) 17 refs.

## Welding

**083613 POLYMER WELDING RELATIONS INVESTIGATED BY A LAP SHEAR JOINT METHOD.** A lap shear joint method was used to study strength development during welding of polystyrene surfaces. The surfaces previously had not been in contact and care was taken to insure rapid wetting of the interface. The shear stress at failure, was measured at room temperature as a function of contact time, at constant welding temperatures up to 20°C above the glass transition temperature. The polystyrene samples had molecular weights,  $M_n = 143,000$  and  $M_w = 262,000$ . The time to achieve complete healing,  $t_\infty \approx 256$  min at 118°C, was found to be of the same order of magnitude as the viscoelastic relaxation time and also with the time required for a polymer chain to diffuse a distance equal to its root mean square end-to-end vector. (Edited author abstract) 20 refs.

**083614 DEUTERATION EFFECT ON THE COEXISTENCE CURVES OF SEMIDILUTE POLYMER SOLUTIONS.** Phase separation points of semidilute solutions of polystyrene in deuterated cyclohexane were measured and compared with those of polystyrene in protonated cyclohexane. Theoretical calculation of the coexistence curve by using the interaction parameters extracted from small-angle scattering of neutron and X-rays has revealed that the deuteration effect on the coexistence curve is due solely to a shift of  $\theta$  point, the temperature at which the binary cluster integral vanishes, while leaving other factors unaltered. The origin of this feature is briefly discussed. (Author abstract) 5 refs.

## POLYSULFIDES

### Doping

**083615 OPTICAL ABSORPTION AND ESR STUDIES OF POLY(p-PHENYLENE SULFIDE) DOPED WITH SULFUR TRIOXIDE.** Optical absorption and ESR spectra of  $SO_3$ -doped poly(p-phenylene sulfide) (PPS) with relatively high conductivity were measured. Two absorption bands were observed at 0.9 and 3.1 eV at the initial doping state. The intensity of these two bands increased with the rise of doping level. ESR spectra with a g-value of 2.0075 were observed for the PPS- $SO_3$  system at the same doping level as that of absorption spectra. In both cases of optical absorption and ESR spectra of  $SO_3$ -doped PPS, the spectral intensity increased slightly under UV-light irradiation, while these spectra were little affected by the near IR-light irradiation. (Edited author abstract) 17 refs.

### Fiber Reinforcement

**083616 POLYPHENYLENE SULPHIDE (PPS).** PPS belongs to the semi-crystalline material group. It is only used with reinforcement fibres and filler for injection moulding and hence there are no transparent grades. Stretched film is crystal clear on account of the small-sized crystallites. The high melting range of around 285°C permits short-term thermal loads of up to 260°C. Polyphenylene sulphide also has excellent inherent flameproofing with its chemical structure of 70% aromatic compounds and 30% sulphur. These products have high resistance to chemicals, even under load and at high temperatures. No solvents are known that dissolve PPS at below 200°C. The low melt viscosity of PPS means that it can take up to 70% filler and/or reinforcement fibre. The new PPS generation with its linear structure brings advantages in mechanical properties and the constancy of the viscosity setting. The weak points of PPS are its low peripheral fibre elongation which results in a low level of toughness and moderate stability vis-a-vis weathering. Shell compounds for electronic components alone are expected to take three times the quantity of encapsulating compound in 1990 as in 1985. 10 refs.

## Pyrolysis

**083617 CHARACTERIZATION OF CURED POLYSULFIDE POLYMERS BY THERMAL DEGRADATION: PYROLYSIS-GC AND THERMOGRAVIMETRIC STUDIES.** Polymers prepared by curing thiol-terminated liquid polysulfide polymer  $[HS(RS_2)_nRSH, R = -CH_2CH_2OCH_2OCH_2CH_2-]$  with p-quinonedioxime,  $PbO_2$ , and  $MnO_2$  were studied by pyrolysis-GC and thermogravimetry. Characteristic differences were observed in the composition of the pyrolyzates under flash pyrolysis at 420 and 470°C. The concentration of the cyclic monomer, 1,3-dioxo-6,7-dithionane, in the pyrolyzates was found to vary considerably from polymer to polymer. The change in mechanism with the extent of degradation and the corresponding overall activation energies were evaluated by thermogravimetry. The pyrolysis-GC and thermogravimetric data were shown to provide partial characterization of the substrates. Mn appears to be in a coordinated complex in the  $MnO_2$ -cured polymer. (Author abstract) 12 refs.

## Sealing

**083619 COMPOUNDING POLYSULPHIDE SEALANTS FOR RESISTANCE TO BIODEGRADATION.** In the early seventies the well established use of polysulphide sealants in water-retaining structures was brought into question by the biological deterioration of a sealant in the Dunkeld Reservoir in Johannesburg. As a result, comprehensive studies were undertaken in South Africa and the UK on the mechanism of the degradation and the factors that influenced it. An accelerated biodegradation test was devised and used to determine the best combination of compounding ingredients for polysulphide sealants that are to be immersed in water. As a result of this work it is now possible to give firm guidelines for the polymer content, curative type and other ingredients to ensure the longevity of polysulphide sealants in any water environment. These recommendations are being confirmed by field trials. Nine years ago a polysulphide sealant designed according to these guidelines was installed in the same Dunkeld Reservoir in Johannesburg. A recent inspection indicated that it is still in perfect condition. (Author abstract) 2 refs.

## Solutions

**083620 KINETICS OF POLYSULFIDE SOLUTIONS: PART III, INVESTIGATION OF HOMOGENEOUS AND ELECTRODE KINETICS BY THE**

**ROTATING DISK METHOD.** The steady-state current density-overpotential relationships for cobalt and platinum rotating disk electrodes in aqueous polysulfide electrolyte (1.3M total  $S_2^{2-}$ , 1M  $S_0$ , and pH=12) were determined over a temperature range of 25–77°C. A model developed to take into account the rate of the homogeneous dissociation of  $S_4^{2-}$  to  $S_2^{2-}$  as well as a finite heterogeneous electrochemical reaction rate yielded parameters consistent with the results of previous transient experiments (in the low overpotential region). At higher overpotentials in the cathodic region a second cathodic reaction was evident. This second cathodic reaction was less prominent when the current densities were lower (as on Pt electrodes) or when the  $S_2^{2-}$  concentrations were higher (as temperature increased). ## Spectroscopic Analysis

**083621 VIBRATIONAL SPECTRA OF SOME CYCLIC POLYSULFIDES.** Vibrational spectra and normal-coordinate analyses using a modified Urey-Bradley force field are reported for 1,2,3,5,6-pentathiepane (lenthionine), 1,3,5,7-tetrathiepane, and 1,2,3-trithiane. Characteristic Raman bands are identified for S-CH<sub>2</sub>-S and S-S-S functionalities in cyclic molecules. The observed and calculated spectra for all the molecules considered here, with the CH stretches omitted for the sake of brevity, are listed. These compounds exhibit antibiotic activity. 26 refs.

## Synthesis

**083622 SYNTHESIS OF INTRAMOLECULARLY CYCLIZED POLY(PHENYLENE SULFIDE)S OF THE THIANTHRENE-TYPE.** Oligomers containing thianthrene units in the chain are synthesized by  $AlCl_3$ -catalyzed reaction of diphenylsulfide, thianthrene, poly(p-phenylene sulfide), and poly(m-phenylene sulfide) with sulfur at 80°C. The products are compared with that obtained by the reaction of diphenylsulfide with  $AlCl_3$  at 225°C. IR spectra and elemental analyses are consistent with cyclic chain structures and show a higher cyclization for  $CHCl_3$ -insoluble fractions. X-ray diffraction analysis indicates the same structure for the samples obtained with the different methods of synthesis. A possible structural model is tentatively proposed. (Author abstract) 25 refs.

**083624 CYCLOPOLYMERIZATION OF DIPROPARGYL SULFIDE BY TRANSITION METAL CATALYSTS.** During the past three decades, extensive studies on the cyclopolymerization of non-conjugated dienes have been made. It was known that group VI metal-based catalysts exhibit a high catalytic activity for the polymeri-

zation of mono- and disubstituted acetylenes. We have also found that  $WCl_6$ - and  $MoCl_5$ -based catalyst systems are very effective for the polymerization of acetylene derivatives containing aromatic heterocycles, and vinyl monomers. The present article deals with the cyclopolymerization of dipropargyl sulfide by  $WCl_6$ - and  $MoCl_5$ -based catalysts. 21 refs.

**083625 SYNTHESIS OF POLYBUTADIENE-POLYSULPHIDE.** The anionic synthesis of polybutadiene-polysulfide polymers from butadiene, elemental sulfur, and sodium was studied in a polar solvent (THF). The polycondensation results from the combination of three reactions: initiation of the monomer by the alkali metals, anionic propagation, and deactivation of the dianionic species on elemental sulfur. From the characterization of the resulting polymers, it has been shown that the sulfur rank of the polymer can be adjusted by varying the ratio  $K=[\text{sodium}]/[\text{sulfur}]$ . The degree of polymerization of the organic chain can be controlled by changing the temperature or the monomer concentration. From the thiol content, it has been concluded that the polysulfide polymers are principally in a cyclic form. (Edited author abstract) 16 refs.

## POLYSULFONAMIDES

### Synthesis

**083626 SYNTHESIS AND PROPERTIES OF POLYSULFONAMIDES CONTAINING THIOPHENE LINKS.** In order to study the synthesis and properties of polysulfonamides containing thiophene links, 2, 2-bis(5-chlorosulfonyl-2-thienyl)propane [BCTP], 2, 2-bis(5-chlorosulfonyl-2-thienyl)butane [BCTB], 1, 1-bis(5-chlorosulfonyl-2-thienyl)cyclohexane [BCTC], and 2,4-dichlorosulfonyl thiophene [DCST] were prepared and interfacial polycondensations with various aliphatic diamines were carried out. The resulting polymers had inherent viscosities in the range of 0.13-0.41 dL/g and showed high extent of moisture absorptions. Most of the polysulfonamides were soluble in electron-donating solvents such as pyridine, DMF, DMSO, NMP, etc. These polysulfonamides exhibited relatively good thermal stabilities. The TGA data revealed 5% weight losses at 275-405°C and residual weights at 500°C were 1-40% under nitrogen. It was also found that dithienylidissulfonyl chlorides produced more thermally stable polymers than DCST, which were comparable to common polysulfonamides from aromatic disulfonyl chlorides. (Author abstract) 15 refs.

**POLYSULFONES** See Also MEMBRANES—Materials; POLYMERS—Blending.

**083627 STUDIES ON THE COPOLYMER COMPOSITION OF SULPHUR DIOXIDE AND PHENYLACETYLENE.** The polysulphone copolymers synthesized from the copolymerization of liquid sulphur dioxide and phenylacetylene in the presence of tert-butyl hydroperoxide at low temperature always have an alternating structure which is independent of solvent, temperature and feed ratio. At a relatively high temperature (50°C) the phenylacetylene/ $SO_2$  system initiated by AIBN gave copolymers with a 1:1 mole ratio, whereas styrene/ $SO_2$  under the same conditions produced copolymers with 2:1 molar ratio. The free radical initiators hydrogen peroxide, m-chloroperbenzoic acid, and diphenyl peroxide were inert at low temperatures. The  $PhC\equiv CH/SO_2$  system with  $(CH_3)_3COOH$  at low temperature is more reactive than  $PhCH=CH_2/SO_2$  but with AIBN at high temperature the reactivities are reversed. These observations suggest

that different mechanisms should operate on the two systems. (Author abstract) 16 refs.

## Applications

**083628 PLASMA-POLYMERIZED MEMBRANES AND GAS PERMEABILITY III.** Plasma-polymerized films of hexamethyldisiloxane were deposited onto various porous substrates having different pore sizes, and the gas permeability of these composite membranes was studied. In each membrane, permselectivity between oxygen and nitrogen was found, but the oxygen permeation rate was different with each substance tested. The minimum thickness of the plasma-polymerized film needed to plug all pores and show permselectivity is about five times the pore radius of the porous substrate. In cases using polysulfone hollow fibers which have high permselectivity, the composite membranes show much higher permeability ratios of oxygen-to-nitrogen than do those of the porous glass hollow fibers. (Edited author abstract) 14 refs.

## Deformation

**083629 SORPTIVE DILATION OF POLYSULFONE AND POLY(ETHYLENE TEREPHTHALATE) FILMS BY HIGH-PRESSURE CARBON DIOXIDE.** Dilation of polysulfone (PSUL) and crystalline poly(ethylene terephthalate) (PET) films accompanying sorption of carbon dioxide is measured by a cathetometer under high pressures up to 50 atm over the temperature range of 35-65°C. Sorptive dilation isotherms of PSUL are concave and convex to the pressure and concentration axes, respectively, and both isotherms exhibit hysteresis. Each dilation isotherm plotted versus pressure and concentration for the  $CO_2$ -PET system shows an inflection point, i.e., a glass transition point, at which the isotherm changes from a nonlinear curve to a straight line. Dilation isotherms of PET below the glass transition point are similar to those of the  $CO_2$ -PSUL system, whereas the isotherms above the glass transition point are linear and exhibit no hysteresis. Partial molar volumes of  $CO_2$  in these polymers are determined from data of sorptive dilation. On the basis of the extended dual-mode sorption model and the current data, primitive equations for gas-sorptive dilation of glassy polymers are proposed. (Author abstract) 31 refs.

## Fatigue

**083630 FATIGUE BEHAVIOUR OF POROUS POLYSULPHONE SURFACE COATINGS FOR ORTHOPAEDIC APPLICATIONS.** Porous polysulphone (PPSF) has recently been selected as a candidate material for use as a prosthetic surface coating in orthopaedic applications to accommodate 'bone ingrowth' for fixation to the skeletal system. The tension-loaded fatigue behaviour of PPSF was characterized based on the interpretation of stress/life (S/N) data. Results of this investigation indicate that the fatigue life of PPSF is governed by crack propagation across the sintered necks of the porous structure. In addition, experimental data revealed that the fatigue strength-reduction factor,  $K_f$ , remains equivalent to the tensile notch strength-reduction factor for a wide range of fatigue lives. However, analytical results indicate that the material has a low notch sensitivity and that a single application of a theoretical elastic stress-concentration factor in a fatigue analysis would be inappropriate. (Author abstract) 8 refs.

## Heat Resisting

**083631 POLYSULPHONE AND POLYETHER SULPHONE (PSU AND PES).** Thermoplastics with a high heat resistance, such as polysulphone (PSU) and polyether sulphone (PES) are gaining increasing importance. Forecasts for the growth in demand are generally optimistic. The rise in demand for high temperature resistant thermoplastics is due foremost to the trend towards miniaturisation in a large number of fields of application, particularly in electrical engineering and the electronic industry, which is going hand in hand with more stringent requirements in terms of heat distortion temperature, heat ageing behaviour and dimensional stability. These thermoplastics which can withstand high temperatures and mechanical stressing are opening up new applications, for reasons of production engineering and weight savings, and are coming to replace conventional materials such as glass, ceramics and metals in a large number of cases. 3 refs.

## Modification

**083632 MODIFICATION OF POLYSULFONE BY METALATION.** Our studies of changes in membrane characteristics brought about by various types of functional groups led to the development of this versatile modification approach in which a diverse range of substituted polymers are attainable. In this letter, the position and degree of lithiation was examined by <sup>1</sup>H-NMR spectral analysis of two simple derivatives. Polysulfone was controllably lithiated by n-butyllithium in THF at temperatures of 0°C and below. The reaction proceeded rapidly and homogeneously in high yield and required little or no excess of reagent and no catalyst. <sup>1</sup>H-NMR analysis of the methyl and deuterio derivatives indicated that the site of lithiation was at the ortho-sulfone position. Up to two lithium atoms per repeat unit were readily substituted, although lower degrees of substitution were obviously equally readily attainable. The high degree of substitution possible by direct metalation is somewhat unusual in low molecular weight systems and exceptional in polymeric systems where lower degrees of substitution and poor regiospecificity and control are typical. Lithiation is a versatile method of polysulfone modification because of the known reactivity of lithium aryls with numerous electrophiles. 15 refs.

## Molecular Structure

**083633 CHARACTERIZATION OF ACRYLIC ACID SULFUR DIOXIDE COPOLYMERS BY CARBON-113 NMR SPECTROSCOPY.** The synthesis and characterization of polysulfones derived from the free radical addition copolymerization of liquid sulfur dioxide with olefins or acetylenes has been the subject of several research publications. However, polysulfones made from the addition of sulfur dioxide to vinyl systems having electron-withdrawing groups directly attached to vinyl carbons are rare. A few years ago we reported the synthesis of several acrylic acid-SO<sub>2</sub> copolymers using low-temperature free-radical-addition polymerization techniques. In this note we examine systematically the structure of some of these copolymers by high field carbon-13 NMR spectroscopy. 16 Refs.

## Phase Transitions

**083634 INVESTIGATION OF THE TRANSITIONS OF OLIGO-POLYSULFONES BY DSC.** The transitions of bisphenol A and phenolphthalein oligopolysulfones were investigated by DSC. It is found that both the oligomers have three transitions within the temperature range (230-550K) studied. Considering the strong dependence of the appearance of the two transitions, lower and higher than T<sub>g</sub> on the specimens' thermal history, i.e., temperature and time of heat-treatment, and their particular molecular structure, it is proposed that these two transitions are morphological in origin and are due to the disordering of relatively short range order of very small regions, and to the disordering of relatively well-ordered intra- or/and intermolecular segments, respectively. Equations for linear relationship between T<sub>g</sub> and 1/M<sup>n</sup> for both the oligomers are given in the paper. (Author abstract) 12 refs.

## Spectroscopic Analysis

**083636 INVESTIGATION OF THE COMPOSITION OF LOW MOLECULAR MASS FRACTIONS OF POLYSULFONES BY MASS SPECTROMETRY.** The consumption of low molecular mass fractions of three aromatic polysulphones has been established for the first time by the mass spectrometry of electron collisions and of field desorption. The advantages of the mass spectrometry of fields adsorption over the mass spectrometry of electron collisions in studying low volatility oligomeric compounds are indicated. It is shown that hydrolysis and cyclization reactions are of a general character in the synthesis of the polysulphones studied, and that the latter reaction is probably one of the main secondary reactions. (Author abstract) 12 refs.

**083638 TEFLON TOUCHES GOLD.** This year is the 50th anniversary of the serendipitous discovery of poly(tetrafluoroethylene) (PTFE). The first fluorocarbon to be commercialised, PTFE is the slipperiest solid in the world, an excellent electrical insulator, displays remarkable antistick behavior, and is renowned for its chemical inertness, insolubility, weatherability and impermeability to moisture. Indispensable now in industrial, aerospace and military circles, non-stick saucepans, and fire protection is used in devices. (Edited author abstract)

Banks, R.E. (UMIST, Manchester, Engl). *Chem Br* v 24 n 5 May 1988 p 453-454.

**083639 TEFLON-WORLD'S SLIPPERIEST SUBSTANCE-WAS DISCOVERED BY ACCIDENT.** The molecular structure of 'Teflon' is a basic chain of carbon atoms, the same as all marketable fluoropolymers, in 'Teflon' this chain is completely surrounded by fluorine atoms. The bond between carbon and fluorine is very strong, and the fluorine atoms shield the vulnerable carbon chain. This unusual structure gives 'Teflon' its unique properties. In addition to its extreme slipperiness, it is inert to almost every known chemical. It has excellent electrical characteristics. It is useful over a remarkably wide temperature range, from 500°F to -400°F. 'Teflon' resin is an excellent material for piping ground water samples against contamination better than alternative materials such as PVC, glass or stainless steel. It can withstand many years of exposure to chemicals, bacteria and moisture.

## Blending

**083640 IONIC MISCIBILITY ENHANCEMENT IN POLY(TETRAFLUOROETHYLENE)/ POLY(ETHYLACRYLATE) BLENDS. I. DYNAMIC MECHANICAL STUDIES.** It is shown that ion-ion interactions resulting from a photon transfer induce considerable miscibility in blends of functionalized poly(tetrafluoroethylene) with ethyl acrylate copolymers containing 4-vinyl pyridine. Dynamic mechanical measurements, in conjunction with transparency of the samples, are used to evaluate miscibility. It is shown that mixing conditions exert a profound effect on the properties of the final blend. The glass transition of the blend is shown to be strong function of the blend composition, as is characteristic of highly miscible systems. (Author abstract). 41 Refs.

## Dielectric Properties

**083643 EFFECTS OF ABSORBED BENZENE ON RELAXATION BEHAVIOR OF POLYTRIFLUOROETHYLENE.** Relaxation behavior in polytrifluoroethylene (PTFE) with varied crystallinity and swollen with benzene was investigated by mechanical and dielectric measurements. PTFE showed the  $\alpha$ ,  $\beta$ , and  $\beta'$  relaxation in decreasing order of temperature. The  $\beta$  relaxation observed around  $-20^\circ\text{C}$  at 100 Hz was considered to consist of components assigned to the amorphous and crystalline regions. The  $\beta'$  relaxation found in a lower temperature region below  $-50^\circ\text{C}$  was related to molecular motions around the defects of anomalous linkages such as head-to-head and tail-to-tail. In swollen PTFE, the  $\alpha$  relaxation due to the micro-Brownian motions of main chains shifted from  $50^\circ\text{C}$  to  $-10^\circ\text{C}$  in mechanical measurements. The  $\beta$  relaxation for swollen samples decreased in intensity or vanished. (Edited author abstract) 14 refs.

## Etching

**083644 THERMAL DESORPTION MASS SPECTROMETRIC AND X-RAY PHOTOELECTRON STUDIES OF ETCHED SURFACES OF POLYTETRAFLUOROETHYLENE.** The etching of polytetrafluoroethylene (PTFE) with Na solutions is known to lead to a loss of F, a loss which is correlated with enhanced adhesion. Subsequent heating partially restores surface F with a concurrent loss of adhesion strength. The authors have combined X-ray photoelectron spectroscopy (XPS) and gas phase mass spectroscopy for in situ measurements of the processes that occur as the fluorocarbon is heated. An array of volatile products, which vary with the specific treatment, desorb from etched PTFE. XPS measurements show that etching produces a major loss of surface F and a gain of surface O. The latter probably results from the subsequent rinse steps. Heating produces a substantial recovery in surface F with only a small decrease in the surface O, and the gain in surface F is shown to occur at a higher temperature than the desorption of any species from the surface. Thus, desorption of products from the surface is decoupled, in terms of both the distribution of products and their relative temperatures, from the surface changes as monitored by XPS. This decoupling suggests that the increase in surface F results from diffusion of low molecular weight fluorocarbons from the bulk or a transition region, or from a rearrangement of the sponge-like surface region produced in the etching process. (Edited author abstract) 10 refs.

**083645 INFLUENCE OF DEBRIS INCLUSION ON ABRASIVE WEAR RELATIONSHIPS OF PTFE.** This paper describes an examination of the relationship between the abrasive wear of a series of  $\gamma$ -irradiated polytetrafluoroethylene samples and some of their mechanical properties. The central theme of the paper is an examination of the correlation of the wear rate  $(\sigma\epsilon)^{-1}$ , where  $\sigma$  and  $\epsilon$  are the stress and strain to rupture in tension, respectively. In the first instance, the simple correlation is quite nonlinear and far from proportional. A major reason for the indifferent quality of the correlation is ascribed to topographical modification of the counterface by debris inclusion. An empirically based means of correcting for this process is proposed. Additional elements have also been included to account for the amount of work expended, the effective local volume deformation and the damage efficiency of the deformation work. (Edited author abstract) 23 refs.

**083646 IN VIVO ANTITHROMBOGENICITY OF POLY(TETRAFLUOROETHYLENE) RADIATION-GRAFT COPOLYMERIZED WITH ACRYLAMIDE.** In order to prepare an antithrombogenic material by making polymer surfaces hydrophilic, acrylamide (AAM) was radiation-graft copolymerized onto poly(tetrafluoroethylene) (PTFE) tubes by preirradiation in Ar and treatment with a monomer aqueous solution. The grafting percentage determined from the weight increment was so small that the surface grafting percentage was calculated by ESCA for the grafted tubes. The in vivo antithrombogenicity was evaluated by relative patent time in the implantation into canine peripheral veins and its relation to the contact angle of water or surface grafting percentage was discussed. From the results of ESCA measured at the photoelectron takeoff angles of  $15^\circ$  and  $90^\circ$ , the graft copolymerization was suggested to proceed into a deep layer from a surface thin layer with low grafting. (Edited author abstract) 11 refs. In Japanese.

## Optical Properties

**083647 LIGHT-SCATTERING CHARACTERIZATION OF POLY(TETRAFLUOROETHYLENE).** Laser light scattering including angular dependence of absolute integrated scattered intensity and of the spectral distribution has been used successfully, for the first time, to characterize a tetrafluoroethylene polymer in oligomers of poly(chlorotrifluoroethylene) at  $340^\circ\text{C}$ . Precise measurements of the intensity-intensity time correlation function permit us to make a Laplace inversion using a variety of techniques including a multiexponential singular value decomposition (MSVD), regularized inversion of Laplace integral equation (RILE), and the CONTIN algorithm developed by S.W. Provencher. We were able to obtain an estimate of the normalized characteristic line-width distribution which could be reduced to a distribution of translation diffusion coefficient at infinite dilution, independent of the method used in the Laplace inversion. (Edited author abstract) 19 refs.

Chu, Benjamin (State Univ of New York at Stony Brook, Stony Brook, NY); Wu, Chi; Buck, Warren. *Macromolecules* v 21 n 2 Feb 1988 p 397-402.

## Order-Disorder

**083648 TEMPERATURE DEPENDENCE OF THE INTRAMOLECULAR DISORDER IN THE HIGH-TEMPERATURE PHASE OF POLY(TETRAFLUOROETHYLENE) (PHASE D).** Calculations of Fourier transforms for bundles of helices suggest that increasing the number of helix reversals should increasingly narrow the profile of the single layer line. On the basis of the reasonable assumption that the number of helix reversals increases with temperature, this narrowing of the line profile with temperature is to be expected. In order to verify this expectation, we have determined X-ray diffraction patterns for the region corresponding to the seventh and eighth layer lines over the temperature range  $20$ – $160^\circ\text{C}$ . Calculations suggest that intramolecular defects which do not involve inversions cannot account for the collapse of the two layer lines of the experimental patterns. The Fourier transform calculations indicate instead that even small variations in the number of reversals can account for dramatic changes in the experimental patterns. 11 refs.

## Oxidation

**083649 REDUCTION IN THE ANTITHROMBOGENICITY OF POLYTETRAFLUOROETHYLENE AND POLYETHYLENE CAUSED BY RADIATION-INDUCED OXIDATION.** To examine the influence of radiation-induced oxidation on the antithrombogenicity of polymers, polytetrafluoroethylene (PTFE) and low density polyethylene (PE) tubes were irradiated with gamma-ray and then treated with water at  $50^\circ\text{C}$ , and surface characterization and evaluation of their antithrombogenicity were carried out. Irradiation was carried out mainly in argon with  $0.14$ – $0.47$  MR for PTFE and in air or water with  $0.44$ – $8$  MR for PE. Data of ESCA and zeta-potential showed the introduction of oxygen-containing groups onto the irradiated surfaces (ca.  $10$  mol% for the irradiated PE), and the contact angle of water for the PTFE and PE surfaces decreased to  $98^\circ$  and  $80^\circ$ , respectively. The relative patent time in canine peripheral veins reduced markedly with dose. The reduction in the antithrombogenicity of the irradiated surfaces is mainly due to the enhancement of platelet activation resulting from a decrease in hydrophobicity of the surfaces. (Edited author abstract) In Japanese. 28 refs.

## Physical Properties

**083650 MELTING TEMPERATURE OF POLYTETRAFLUOROETHYLENE.** The equilibrium melting temperature of polytetrafluoroethylene (PTFE), i.e., the melting temperature of its most perfect crystals, is generally accepted to be  $327^\circ\text{C}$ . Using differential scanning calorimetry (DSC) at  $10^\circ\text{C min}^{-1}$ , the virgin (as-polymerized) PTFE exhibits a melting temperature ( $T_m$ ) of about  $342\pm 2^\circ\text{C}$ ; the corresponding  $T_m$  of a sintered PTFE (melt-crystallized) being  $328\pm 2^\circ\text{C}$ . This letter comments on the two melting temperatures of PTFE because the issue has not been addressed clearly in the literature. 5 Refs.

## Pyrolysis

**083652 DEPOLIMERYZACJA POLITETRAFLUOROETYLENU.** [Depolymerization of Polytetrafluoroethylene (PTFE)]. The results of studies on the process of PTFE pyrolysis as a method of Tarflen waste utilization are presented. (Tarflen is a Teflon-like material, produced at Nitrogen Works in Tarnow). Possible applications of reaction products are discussed. (Author abstract) In Polish. 5 refs.

Miesowicz, Halina. *Przem Chem* v 66 n 7 Jul 1987 p 333-335.

## Radiation Effects

**083653 TRANSIENT PHOTOCURRENTS ACCOMPANYING IRRADIATION OF CHARGED FILMS OF POLYTETRAFLUOROETHYLENE.** It was established experimentally that the transient photocurrents arising when PTFE films charged in a corona discharge are illuminated are reversible. It is shown that the transient current is of a thermal origin and is formed by the superposition of two oppositely directed components. The characteristics of the photocurrents are explained by the existence of internal polarization (heterocharge), arising in a strong field generated by the homocharge trapped on the surface, in the films. The existence of heterocharge in nonpolar films indicates that it is in principle possible to make stable electrets, in which the potential is maintained constant owing to slow self-consistent relaxation of the homo- and heterocharge. (Author abstract) 6 refs.

## Reviews

**083655 PTFE: 50 YEARS OLD.** A historical review of polytetrafluoroethylene (PTFE), now known as 'Teflon,' is presented. The chemical, mechanical, and physical properties are reviewed.

Anon. *Aerosp Eng (Warrendale PA)* v 8 n 4 Apr 1988 p 31-34.

## Rheology

**083656 ELECTRO-OPTIC AND RHEOLOGICAL BEHAVIOUR OF AQUEOUS DISPERSIONS OF POLYTETRAFLUOROETHYLENE (PTFE) FIBRILS.** Electro-optic and rheological measurements were carried out on PTFE-fibrils. The crystalline fibrils had an axial

ratio of about 100 and a thickness of 200 Angstrom. The dispersions were stabilized by ionic perfluorosurfactants and could be kept for months without precipitation. The rotational diffusion constant of the fibrils was determined as a function of the volume fraction. Both electric birefringence and rheological measurements gave identical results for the orientation times. In the dilute and semidilute concentration range the rotational diffusion constant was the same and did not change at the overlap concentration. The shear modulus was found to increase in the semidilute concentration with the square of the volume fraction of the PTFE fibrils. (Edited author abstract) 21 refs.

## Thermal Conductivity

**083657 THERMAL CONDUCTIVITY OF F-4 PTFE AT 5-310°K.** F-4 PTFE (polytetrafluoroethylene) belongs to the class of polymeric materials in which crystals are linked together by amorphous parts. Two phase transitions occur in F-4 PTFE: at 293 and 303°K. The thermal conductivity of PTFE has been examined with a standard system. Four specimens were examined made from a single batch of material. 3 refs.

Medvedev, V.A.; Sviridenko, V.I.; Rybkin, N.P.; Gorbunova, V.G. *Meas Tech* v 30 n 5 May 1987 p 459-460.

## Thermal Properties

**083658 THERMAL CHARACTERISTICS OF IRRADIATED POLYTETRAFLUOROETHYLENE.** This work investigates the influence of irradiation on the heat conductivity, density and linear thermal expansion coefficient  $\beta$  of PTFE to clarify the specifics of the action of such parameters as temperature of irradiation  $T_{rad}$ , the power of the absorbed dose  $P$  over a wide temperature range of measurement  $T_{meas}$  and absorbed doses and seeks to define the mechanism of the radiation changes for high radiation doses. A mechanism of the radiation changes in the properties of PTFE on the basis of analysis of the behavior of the crystalline and amorphous phases is proposed. (Edited author abstract) 16 refs.

Briskman, B.A. (Karpov Physicochemical Inst, USSR); Rozman, S.I. *Polym Sci USSR* v 28 n 6 1986 p 1388-1396.

## Thermodynamic Properties

**083659 HEAT CAPACITIES AND ENTROPIES OF LIQUID POLYFLUOROETHYLENES AND POLYCHLOROETHYLENES.** Heat capacities in the solid state for the homologous series of linear macromolecules consisting of polyethylene (PE), poly(vinyl fluoride) (PVF), poly(vinylidene fluoride) (PVF2), polytrifluoroethylene (P3FE), and polytetrafluoroethylene (PTFE), as well as poly(vinyl chloride) (PVC), poly(vinylidene chloride) (PVC2), and polychlorotrifluoroethylene (PC3FE) were recently analyzed by the authors. Prediction schemes for the heat capacity were based on the additive group vibrations and the mass-dependent  $\Theta$  temperatures of Tarasov approximations. In this research they continue this work and present data for the liquid state. Prior, extensive analyses were available only for liquid polyethylene and polytetrafluoroethylene. With heat capacities of solid and liquid states and transition parameters, it is possible to establish enthalpies, entropies, and Gibbs free energies over the whole temperature range. This establishment of thermodynamic functions is one of the main goals of ATHAS, laboratory of Advanced Thermal Analysis. 23 refs.

## Thin Films

**083660 INVESTIGATION OF PTFE TRANSFER FILMS BY INFRARED EMISSION SPECTROSCOPY AND PHASE-LOCKED ELLIPSOMETRY.** When a PTFE sheet was rubbed unidirectionally over a smooth surface of stainless steel, an essentially monomolecular transfer film was formed. By ellipsometric and emission infrared spectroscopic techniques it was shown that the film was 10 to 15 Angstrom thick and birefringent. From the intensity differences of infrared bands obtained with a polarizer passing radiation polarized in mutually perpendicular planes, it was possible to deduce transfer film orientation with the direction of rubbing. After standing in air for several weeks the transfer films apparently increased in thickness by as much as threefold. At the same time both the index of refraction and the absorption index decreased. Examination of the surfaces showed that the films had become porous and flaky. The coefficients of friction decreased with the formation of the transfer film but increased again as the film developed breaks. (Edited author abstract) 9 refs.

## Wear

**083661 MOLECULE STRUCTURE VARIATIONS IN FRICTION OF STAINLESS STEEL/PTFE AND ITS COMPOSITE.** The friction and wear characteristics of PTFE and one of its composites, JS material rubbing against stainless steel, were determined with a pin-disk tester in this study. The JS material is a multilayer composite composed of PTFE layer containing metal oxide and others, porous bronze layer, copper-plating layer and steel back. The submicroscopic features of frictional surfaces of stainless steel and JS materials were observed with an electron probe microanalyzer. The determination of JS material wear debris with electron spin resonance spectroscopy showed that polymeric radicals different in structure and stable in air existed. The authors consider that these PTFE molecule structure variations might be of benefit to the adhesion of PTFE transfer film to the rubbed stainless steel surface, which is important to improve the friction and wear performance of PTFE. (Edited author abstract) 14 refs.

**083663 EFFECT OF NETWORK CHAIN-LENGTH DISTRIBUTION, SPECIFICALLY BIMODALITY, ON STRAIN-INDUCED CRYSTALLIZATION.** Polyurethane elastomers were prepared from a series of

poly(ethylene oxide) samples by end-linking the chains into 'model' trifunctional networks. The molecular weight  $M_c$  between crosslinks in such networks is simply the number-average molecular weight  $M_n$  of the precursor polymer. End-linking samples separately gave networks with unimodal distributions of network chain lengths, whereas end-linking mixtures of two samples having very different values of  $M_n$  gave bimodal distributions with average values of  $M_c$  equal to the average value of  $M_n$  for the two samples. Stress-strain isotherms in elongation were obtained for these networks, both unswollen and swollen to various extents. Strain-induced crystallization was manifested in elastic properties that changed significantly with changes in temperature. (Edited author abstract) 24 refs.

**083665 WATERBORNE RESINS.** The urethane chemistry to make polymers is based on the reactions of polyisocyanates with diols, in general. The advantages of the polyurethanes lie in their toughness and flexibility, and adhesion can be very good. They can be quite good in clears or pastel colors, when ambient air dried. Disadvantages may lie in their wetting of some substrates, but standard compounding (dispersant or surfactant additions) can alleviate this. ?

Athey, Robert D. Jr. (Athey Technologies, El Cerrito, CA, USA). *Met Finish* v 85 n 10 Oct 1987 p 61.

**083666 HIGH-EFFICIENCY FLAME RETARDANT FOR FLEXIBLE POLYURETHANE FOAM.** The halogenated ester, Firemaster 836, is a highly efficient flame-retardant additive for flexible polyurethane foam. Test results demonstrate its efficiency compared with other products, and the low levels required minimize adverse effects on foam physical properties. Developed specifically for flame-retarding foam for automotive interiors and furniture, it is a cost-effective alternative to flexible polyurethane foam formulations for meeting today's flammability-test requirements.

**083667 FIFTY YEARS OF POLYURETHANE.** Polyurethane celebrated its 50th anniversary in November of 1987. Used extensively as a rigid foam in the construction industry, the patent issued to Bayer AG in 1937 is credited as the starting point for the development of this polymer. The article covers the history and applications of polyurethanes.

Anon. *Insul J (Rickmansworth Engl)* v 31 n 9 Dec 1987 p 22-24.

**083668 VERSATILITY OF IN-SITU POLYURETHANE FOAM.** The use of rigid, low density polyurethane foam for insulation purposes is widespread throughout the world with approximately one million tons of raw materials being sold for this purpose. The principal reasons for the continued growth of polyurethanes are insulation efficiency, ease and versatility of fabrication and long term ageing properties. The advantage of on-site

application is that it allows the insulation of non-regular surfaces as well as the facility to insulate areas where access is difficult, (particularly pipework and narrow cavities). The article highlights some of the important trends in in-situ foaming, covering both spray-applied and liquid-dispersed molecules.

## Additives

**083670 USE OF 2,6-TOLUENEDIISOCYANATE IN POLYURETHANE CAST ELASTOMERS.** A study of the use of 2,6-toluenediisocyanate (2,6-TDI) in polyurethanes was made by comparing polymers made with pure 2,6-TDI to an 80/20 isomeric blend of 2,4/2,6-TDI and to pure 2,4-TDI. Prepolymers were prepared using three different types of polyols [polybutylene adipate, polycaprolactone, and poly(oxytetramethylene glycol)] which were end-capped with the three TDI systems. In systems using the 2,6-TDI end-capped polyether, reactivity increased, but only small or insignificant changes were observed for hardness, moduli, elongation, tear resistance, and tear propagation resistance. The increases or decreases in properties due to 2,6-TDI can be attributed to the effects of the increased symmetry in the 2,6-TDI isomer compared to the 2,4-TDI. These effects may be made manifest via increased crystallinity and more efficient separation of the hard and soft segments in the polyurethane matrix. (Edited author abstract) 7 refs.

**Adhesives** See Also WOOD PRODUCTS—Gluing.

**083671 POLYURETHANE-BASED SEALANTS MODIFIED BY BLENDING WITH KRAFT LIGNIN.** An investigation was conducted to establish the viability of blending Kraft lignin (L), a naturally occurring, readily available polymer resource, with polyurethane (PU) based sealants. The sealants were tested in a detailed program where lignin-sealant blends, having blend ratios varying between 0 and 20 pbw L, were prepared on substrates of aluminum, mortar, and wood, and subjected to laboratory control (C), artificial weathering (AW), and natural weathering (NW) conditions. Results of tension testing showed that generally, lignin acts as a reinforcing agent which adds rigidity to the polymeric matrix, as indicated by the increase in toughness and modulus of blended sealants with the addition of lignin. In addition, the curing mode of PU, as determined by sequence hardness testing, was modified with the addition of lignin. (Edited author abstract) 12 refs.

**083673 PROGRESS IN POLYURETHANE ELASTOMERS.** Until recently a product made from a cast or injection moulded polyurethane has always been more expensive than a similar one made from a conventional rubber or plastic and hence its use was only justified by complicated long term cost-performance calculations. Whilst this remains the situation for most types of PUs, it is also now possible using the automated reaction injected molding (RIM) process to make products which are cost competitive with other rubbers and plastics and which also possess superior properties. Hence, especially in the automotive field PU usage is rapidly increasing. This review is organized into materials followed by application technology. (Edited author abstract) 44 refs.

Hepburn, Claude (Loughborough Univ of Technology, Loughborough, Engl). *Progr Rubber Plast Technol* v 3 n 3 1987 p 33-52.

**083674 EXTRACTION CAPACITY OF MACROCYCLIC POLYURETHANOURAES.** The extraction and complexing capacity of polyurethanoureas, containing macrocyclic dibenzo-18-crown-6 in the main chain, was studied. The extraction capacity of these polymers was determined, and extraction equilibrium constants were calculated. It was established that polyurethanoureas with macrocyclic ligands possess a higher complexing and extraction capacity for metal ions, in comparison with the initial dibenzo-18-crown-6. (Author abstract) 9 refs.

Veselov, V.Ya.; Zhurilo, A.A.; Grekov, A.P. *Sov Prog Chem* v 53 n 9 1987 p 103-105.

**083675 NEW DEVELOPMENTS IN ALIPHATIC POLYURETHANES.** Continued new developments have been made in the following areas of Light Stable Aliphatic Polyurethanes: (1) Film composites for optical applications, (2) Aliphatic polyurethane coatings and films, (3) Aliphatic Polyurethane adhesives for a variety of optical and non-optical applications, (4) Post curable hot-melt adhesive and film applications, (5) Novel medical applications for specialty aliphatic polyurethane elastomeric systems which have a vast potential in several medical use areas. A variety of aliphatic and pseudoaliphatic polyisocyanates have been employed to produce both coating films and elastomers having novel applications in a variety of technological areas. A variety of application methods have been explored to broaden the technological areas of elastomeric film formation for various end use applications. These areas cover a broad range of product application from preformed elastomeric film to moisture and chemically post-cured elastomers that cover the marketing potential that can be seen in each of the above technological areas. (Edited author abstract)

Gary, H.E. (K.J. Quinn & Co, Malden, MA, USA); Willwerth, L. *J Elastomers Plast* v 20 n 1 Jan 1988 p 46-53.

**083676 APPLICATIONS FOR POLYURETHANES: ADHESIVES, SEALANTS, BINDERS.** Polyurethane adhesives and sealants are used in a wide variety of applications, including shoes, laminating, moisture cure adhesives, structural bonding and hot melt urethanes. It is shown that polyurethane binding applications range from foundry binders to binders for wood, flexible urethane foam, rubber scraps, agricultural products and glass fibers. The authors indicate that as the chemistry and the materials available to the urethane industry continue to grow, new types of polymers for adhesives and sealant applications will be developed. The increase in laminates, the variety of plastics and the direction towards lighter weight structures act as a driving force for the expansion of urethane adhesives and sealants. The ability of urethanes to be molecularly engineered for specific applications and their compatibility with a great variety of polymers are major factors for the continued growth of urethane systems. 10 Refs.

### Biodegradation

**083677 ANALYSIS OF IN VITRO ENZYMIC AND OXIDATIVE DEGRADATION OF POLYURETHANES.** In vitro biodegradation studies were performed to assess the long-term stability of poly(ether urethane) (PEU) implants. Three PEUs and one poly(ester urethane) were treated with enzymes characteristics of those released from inflammatory cells during the foreign body reaction. In addition, the effect of hydrogen peroxide was observed to examine oxidative degradation. Polymers were prepared as thin films on glass, gold, silver, and copper substrates to test the possibility of metal-catalyzed degradation. Molecular weights and polydispersities of the polymers were measured by gel permeation chromatography (GPC) before and after treatment. Changes in peak shape and location were also monitored. The results demonstrate that varying degrees of both enzymatic and oxidative degradation occurred. (Author abstract)

Ratner, B.D. (Univ of Washington, Seattle, WA, USA); Gladhill, K.W.; Horbett, T.A. *J Biomed Mater Res* v 22 n 6 Jun 1988 p 509-527.

### Blending

**083678 PREPARATION AND CHARACTERISTICS OF POLYURETHANE AND HALOGENATED POLYMER BLENDS FOR MULTI-FUNCTIONAL WETTING COAGULATING COATING.** Blends of a polyurethane elastomer and polyvinyl chloride or polyvinylidene fluoride were obtained through precipitation from DMF solvent. Studies on the compatibility of the blends were carried out using DSC, Rheovibron, infrared spectroscopy, SEM and TEM. The tensile properties and the thermal stability of these blends were investigated through the use of stress-strain curves and DAT-TG thermogram. The study also included coagulative behaviours in different coagulating conditions (temperature and composition of the coagulation bath). PU/PVC blends are compatible and can be made into porous films which possess high vapour permeability under certain conditions. However PU/PVDF blends are incompatible. (Author abstract). 11 Refs.

**Casting** See Also ELASTOMERS.

**083679 ROYALCAST CASTABLE PLASTICS: A GROWTH OPPORTUNITY FOR THE POLYURETHANE CASTER.** Casting is a proven cost effective production method for satisfying certain part requirements (size, shape, quantity). Polyurethane casters generally have been limited by material and market opportunities to flexible applications. Now with the development of

castable plastics, such as Royalcast, the molder can also produce rigid parts. Thus, by utilizing existing equipment, casting expertise, and Royalcast, the polyurethane caster will be able to compete against metal and other rigid materials and enjoy new growth opportunities.

Zawacki, Chester A. (Uniroyal Chemical Co, Middlebury, CT, USA). *Elastomerics* v 120 n 4 Apr 1988 p 20-22.

### Chemical Analysis

**083680 FORMULATING POLYURETHANE ADHESIVES AND SEALANTS.** This article is the first in a series of two on polyurethane adhesives and sealants. In this segment, the authors discuss the formulation of polyurethanes. Raw materials are also covered, including isocyanates, polyols, chain extenders, catalysts, and solvents and additives. The authors also discuss one- and two-component adhesives and sealants.

### Coatings

**083681 POLYURETHANE COATINGS FOR INTEGRATED OPTICS APPLICATIONS.** It is reported that optical waveguides can be fabricated using polymers based on polyurethane and the refractive index can be varied from 1.563 to 1.595 by changing the relative concentrations of various components. Coatings based on polyurethane were prepared by reacting a hydroxyl-terminated compound with an isocyanate resulting in a methane linkage. A large number of optical waveguides of various thicknesses were fabricated using these polyurethane coatings. An initial assessment of the quality of the waveguides was made by measuring the propagation losses in the films. The losses in the waveguides based on polyester were significantly higher than those based on acrylic polyol. 9 Refs.

### Combustion

**083682 REVIEW OF THE LITERATURE ON THE GASEOUS PRODUCTS AND TOXICITY GENERATED FROM THE PYROLYSIS AND COMBUSTION OF RIGID POLYURETHANE FOAMS.** The literature on rigid polyurethane foam has been reviewed with an emphasis on the gaseous products generated under various thermal decomposition conditions and the toxicity of those products. This review is limited to publications in English through 1984. Carbon monoxide (CO) and hydrogen cyanide (HCN) were the predominant toxicants found among more than a hundred other gaseous products. The generation of CO and HCN was found to increase with increasing combustion temperatures. Many test methods were used to assess the acute inhalation toxicity of combustion products from various rigid polyurethane foams. Lethality, incapacitation, physiological and biochemical parameters were employed as biological end points. In general, the combustion products generated from rigid polyurethane foam in the flaming mode appear to be more toxic than those produced in the non-flaming mode. (Edited author abstract) 84 refs.

### Crosslinking

**083683 CORRELATION OF MECHANICAL PROPERTY, CROSSLINK DENSITY AND THERMOGRAVIMETRIC BEHAVIOR OF CASTOR OIL POLYURETHANE-POLYSTYRENE DIVINYLBENZENE SIMULTANEOUS IPN NETWORKS.** Several simultaneous interpenetrating networks (IPN) of

castor oil polyurethane (COPUN) and polystyrene divinyl benzene (PSN) were synthesized under conditions where the free radical polymerization of styrene and the crosslinking reaction of castor oil and toluene diisocyanate progress at comparable rates. Comparison of the mechanical properties and crosslink density of the COPUN and COPUN/PSN-IPNs indicates a marginal increase in tensile strength and crosslink density from COPUN to 60COPUN/40 PSN IPN. IPN samples prepared with further increased PSN content show steady decrease in the above properties. This reversal of the expected trend was attributed to the possible greater molecular interpenetration achieved due to similar gelation times with resultant extension of chains and increase in free volume between crosslinks. This was further confirmed from thermogravimetric data on the initial stages of decomposition of the IPNs. (Author abstract) 17 refs.

Kumar, V.G. (Vikram Sarabhai Space Cent, Trivandrum, India); Rama Rao, M.; Guruprasad, T.R.; Rao, K.V.C. *J Appl Polym Sci* v 34 n 5 Oct 1987 p 1803-1815.

**083684 INTERPENETRATING POLYMER NETWORKS FROM CASTOR OIL-BASED-POLYURETHANES AND POLY(ETHYL ACRYLATE). VII.** Liquid prepolyurethanes were synthesized from castor oil and toluene-2,4-diisocyanate (TDI) under different experimental conditions and varying NCO/OH ratios. All these prepolyurethanes were subsequently reacted with ethyl acrylate/ethylene glycol dimethacrylate mixtures by radical polymerization using benzoyl peroxide as initiator to obtain interpenetrating polymer networks (IPNs) by transfer molding. The novel polyurethane/poly(ethyl acrylate) IPNs are found to be tough films. These IPNs are characterized in terms of their resistance to chemical reagents, thermal behavior (DSC, TGA), mechanical behavior including tensile strength, Young's modulus, and elongation. The dielectric properties, namely electrical conductivity, dielectric constant, dielectric loss, and loss tangent were computed. The mechanothermal behavior was analyzed by dynamic mechanical spectroscopy. The morphological behavior was studied by scanning electron microscopy. (Author abstract) 19 refs.

Patel, Mayur (Sardar Patel Univ, India); Suthar, Bhikhu. *J Appl Polym Sci* v 34 n 5 Oct 1987 p 2037-2045.

**083685 EFFECTS OF CROSSLINKING ON THE DYNAMIC MECHANICAL PROPERTIES OF URETHANES.** The effects of crosslinking on a series of Solithane 113 urethane polymers was analyzed to determine how the material characteristics changed with respect to the glass transition temperature, glassy and rubbery modulus, and loss tangent. Two different sets of data were obtained. Data as a function of temperature were obtained from Polymer Laboratories DMTA and data as a function of frequency from a resonance apparatus crosslink density increases the glass transition temperature and increases the temperature of the peak loss factor density did not reduce the difference in the modulus between the glassy and rubbery regions and only a slight broadening of the loss factor curves was noted. 3 refs.

Madigosky, Walter M. (US Naval Surface Weapons Cent, Silver Spring, MD, USA). *Rubber World* v 196 n 6 Sep 1987 p 27-29.

**083686 DETERMINATION OF THE DEGREE OF CROSSLINKING IN POLYURETHANES BY REACTION ANALYSIS AND GAS CHROMATOGRAPHY.** The method for determination of the degree of crosslinking in the linear polyurethanes from TDI and oligo-(oxyethyleneoxypropylene)bisphenol-A is described. The method is based on selective reaction of imine groups contained in urethane and urea groups of polyurethane with trifluoroacetic anhydride. Resulting product reacts with aniline forming N-phenyltrifluoroacetamide. The amount of N-phenyltrifluoroacetamide is determined by gas chromatography. Basing on this, the content of secondary nitrogen atoms in polyurethane molecule is

calculated. The degree ( $\alpha$ ) of crosslinking is calculated basing on secondary nitrogen atoms content. (Edited author abstract) 6 refs.

## Curing

**083687 BI-CURING POLYURETHANES REACT WITH HEAT OR HUMIDITY.** Bi-curing polyurethane adhesives cure in the presence of heat and/or humidity. This article deals with the properties of and the processing conditions for these materials. The authors also explore applications for these products in the automotive industry. (Author abstract)

Ambrus, Zoltan (Sika Corp, Zurich, Switzerland); Zabel, Lutz. *Adhes Age* v 30 n 12 Nov 1987 p 36-37.

**083688 THREE TESTS TO IMPROVE POLYURETHANE-UREA CURING.** Unstable reactions in the cure of urethane-urea polymers can cause a fall-off in tensile strength and other properties over time. To anticipate and compensate for potential losses, the processor can test solvent absorption and viscosity and apply a new infrared (IR) analysis technique - thus improving quality and efficiency at the curing stage. Fourier transform infrared (FTIR) was used for rapid data acquisition to follow the cure of a polyurethane-urea at 110, 120, and 130°C for prolonged cure times. At the same time, identical samples were prepared and tested by chemical means to show the effects of the changing IR composition on the properties of the elastomer. A kinetic model was used to assign the majority of the more than 30 IR bands that were observed to change during cure. 6 refs.

## Dielectric Properties

**083689 ANALYSIS OF TEMPERATURE-DEPENDENT AC DIELECTRIC LOSS DATA.** The analysis of dielectric loss data is frequently complicated by the presence of ohmic conductivity, especially at lower frequencies. Two simple methods are discussed for locating transition temperatures and for determining activation energies in such cases. In the first method the permittivity derivative is used; in the second, permittivity difference spectra are used. The latter technique, however, cannot be used for activation energy determination. The theoretical basis of these methodologies and an analysis of representative experimental data are presented. The data set include measurements of pure and filled polyurethanes and of radiation-cured unsaturated polyester resins. (Edited author abstract) 14 refs.

## Evaluation

**083690 DESMEARED, SLIT-SMEARED AND PROJECTED SAXS: A COMPARISON OF VARIOUS METHODS OF EVALUATION FOR SEGMENTED POLYURETHANES.** Evaluation methods for X-ray small angle scattering of segmented polyurethane elastomers are discussed using the assumption of isolated, randomly distributed hard segment domains in order to test the reliability of evaluation. Projection of the intensity distribution onto the meridian of the scattering diagram reduces the analysis to a one-dimensional problem. The projection has to be calculated in the three dimensional Fourier space either by desmeared the slit-smeared scattering intensity or by projecting it directly onto the meridian. Practically identical results are obtained by both procedures, so that the desmeared operation may be omitted in the present case. (Edited

author abstract) 15 refs.

## Extrusion

**083691 STUDY ON THE REACTIVE EXTRUSION PROCESS OF POLYURETHANE.** An engineering analysis of the reactive extrusion process of a thermoplastic polyurethane was made through numerical simulation and actual experiment. The reactants used in this system were 4,4'-diphenylmethane diisocyanate, polycaprolactone diol (M.W., 824), and 1,4-butanediol with equivalent weight ratio of 2:1:1. As a catalyst, dibutyltin dilaurate was used. The reaction kinetics and the viscosity function were obtained through experiments, and the mathematical model which includes the conservation equations of mass, momentum, energy, and chemical species was solved numerically to obtain the velocity, concentration, temperature, viscosity, and pressure profiles. The actual experiments were performed in the laboratory scale extruder to compare the experimental results with those of the numerical simulation. (Author abstract) 20 refs.

## Fiber Reinforcement

**083692 NYLON FIBER REINFORCEMENT TO POLYURETHANE COMPOSITES.** The potential of a nylon 6 fiber was evaluated from composite applications involving rigid polyurethane systems. A study showed that the use of COMPET N, a nylon 6 based fiber surface treated to enhance wetout and adhesion, in an ISP polyurethane system results in composites with higher impact values and lower weight than those reinforced with glass fiber. A 2 percent loading of COMPET N matt increased impact values by more than 300 percent over an unreinforced control while a 3 percent loading of glass matt resulted in increases of less than 100 percent. A drop impact test showed COMPET N fabric reinforced composites to absorb twice as much energy as an unreinforced and glass reinforced composite without major damage. (Edited author abstract) 7 refs.

**083694 FINE COLLOIDAL SILICA AS REINFORCING FILLER IN POLYURETHANE POLYMERS.** Colloidal silica in the particle size range 1.4-10 nm was extracted into tetrahydrofuran (THF). Alkali silicate solutions with SiO<sub>2</sub>:M<sub>2</sub>O (M=Li,Na,K,Cs) ratios ranging from 3:1 to 20:1 were used as source of silica particles in the size range 1.4-4.4 nm whereas commercial silica sols were used for particles in the range 5-10 nm. Films of polyester- and polyether-based polyurethane-containing colloidal silica were prepared and their mechanical prop-

erties measured. The reinforcing effect increased with increasing silica content and showed a maximum between 1.5 and 2.5 nm for polyether-based polyurethane and between 4 and 6 nm for polyester-based polyurethane. The area under the hysteresis loops of the stress-strain curves also showed maximum in the same particle size ranges for the two types of polyurethane. Reinforcement mechanisms are discussed in terms of interactions between small particles and hard or soft segments of the polymer chains. (Author abstract) 8 refs.

## Flame Resistance

**083695 FLAME RETARDATION OF POLYURETHANES BY MEANS OF 1,4-BIS(DIALKOXYPHOSPHINYL)HYDROXYMETHYLBENZENE.** New phosphorus-containing homopolyurethanes were synthesized by reacting various diisocyanates such as tolylene diisocyanate, methylenebis(4-phenylisocyanate) and hexamethylene-1,6-diisocyanate with 1,4-bis(dialkoxyphosphinyl)hydroxymethylbenzene (BDAB). In addition, copolyurethanes containing approximately 3% phosphorus were prepared by copolymerization of these diisocyanates with an equimolar amount of BDAB-hydroquinone mixture. BDAB was less reactive towards diisocyanates than hydroquinone due to the electron-withdrawing inductive effect of the phosphinyl groups. The polymers synthesized were characterized by inherent viscosity measurements as well as by proton nuclear magnetic resonance (1H-NMR) and infrared (IR) spectroscopy. Differential thermal analysis (DTA) studies of polymers revealed that the incorporation of BDAB in polyurethanes altered their thermal decomposition mode by increasing the exothermicity due to pyrolysis. (Edited author abstract) 20 refs.

## Flammability

**083696 COMPARTMENT TESTS OF POLYURETHANE FOAM SEATING ASSEMBLIES.** Data from compartment tests of polyurethane foam seating assemblies are reported. Results show that the behavior of such assemblies during fires is strongly dependent on the type and position of interliners and upholstery fabrics. An incidental comparison of peak rate of heat release obtained in a compartment test with a predictive model equation is made and selected data from the tests are presented. (Author abstract) 10 refs.

## Foam

**083698 OPTIMIZED PROCESSING OF MICROCELLULAR POLYURETHANE SYSTEMS THROUGH CATALYST AND SURFACTANT TECHNOLOGY.** The paper entitled 'Novel Elastomeric Catalysts' presented at last year's SPI meeting in Reno, Nevada demonstrated substantial benefits in demold and extended cream for microcellular systems. This paper reviews the status of these catalysts and introduces additional process-

ing advantages for shoe soles identified through additives technology. The authors demonstrate how improved processing advantages can be achieved with the use of non-silicon surfactants. Several areas are investigated such as: improved flow, improved mixing and increased bonding of urethane to urethane. This paper demonstrates quality and productivity advantages through the use of fast cure catalyst in combination with an organic surfactant. (Edited author abstract)

**083699 APPLICATION OF RIGID POLYURETHANE INTEGRAL-SKIN FOAMS TO THERMAL INSULATING UNIT CASES FOR CAR AIR CONDITIONERS.** Integral-skin foams of rigid polyurethane are sandwich structures consisting of a core layer of closed cells enclosed in rigid surface layers on both sides. We examined the layer composition of integral-skin foam with the objective of maximum flexural strength, and then studied possibilities of reconciling the strength and thermal insulating properties in housings for evaporators in car air conditioners; i.e., unit cases. This examination showed that the most practical density range ( $250 \leq \rho(\text{all}) \leq 500 \text{ kg/m}^3$ ) provides vibratile resistance and thermal insulating properties. (Edited author abstract) 14 refs.

**083700 DOWNWARD VERTICAL BURN APPARATUS - A NEW TOOL FOR EVALUATING IGNITION RESISTANT FLEXIBLE POLYURETHANE FOAM.** The Downward Vertical Burn Apparatus is an inexpensive, easily run flammability screening test for severe service foams. Simple evaluation procedures allow estimation of the effect of formulation changes on the burn properties across a broad span of fire development levels. Examination of various classes of foams have provided rankings of ignition resistance which in all cases parallels results from other standardized tests. Time required for DVBA data is approximately 1/10 required for ASTM E-906. Limited correlation data obtained from ASTM E-906 indicates that the heat release rate of foams evaluated at incrementally increased radiant flux conditions correlates with burn rate at incrementally increased oxygen levels on the DVBA. The correlation between DVBA and ASTM E-906 is insufficiently developed to calculate factors for interchanging data between the methods. 5 refs.

**083701 POLYURETHANE FOAM IN THE NBS SMOKE CHAMBER: EFFECT OF VARIATION IN CONDITIONS AND FORMULATION.** A variety of flexible polyurethane foams were tested in the NBS Smoke Chamber over a range of incident radiant fluxes of 0.1 to 2.5  $\text{W/cm}^2$ . The effect of formulation variations on performance and the varying responses to changes in flux were determined. The determination of the dependence of the rate of smoke formation on irradiation conditions is suggested as a possible measure of smoke formation during the early stages of a developing fire. The rate of smoke development may be a more valid measure than total smoke. (Author abstract)

**083704 THERMOGRAVIMETRY OF POLYURETHANE-FOAMED PLASTICS.** Thermogravimetric comparison tests on foamed plastics based on polyether- and polyester-polyurethanes in two different laboratories show that thermogravimetry in combination with derivative thermogravimetry is suited for the characterization of these industrial products when values for the decomposition temperature of the main decomposition reaction (DTG-peak), the residue of thermal decomposition at 600°C and also the apparent activation energy of the main decomposition reaction are available in an exactly defined range of evaluation. In the evaluation of DTG-curves, the DTG-peaks could be correlated with specific structural characteristics of PUR-foamed plastics. (Edited author abstract) 7 refs.

**083705 STRUCTURAL MODEL FOR AIR FLOW IN FLEXIBLE PUR FOAMS.** A new structural model based on the two term fluid flow equation of A.N. Gent and K.C. Rusch is described. The classical theory of flow through porous packed beds is used to relate the permeability and flow inertia coefficients to the average cell diameter, the tortuosity of the flow path and a skin friction coefficient. The model is used to predict how air flow is influenced by compression of the polyurethane (PUR) cellular matrix. Results of laboratory investigations are presented and compared with the model. For the most part good agreement is obtained for compressions up to about 60%. It is shown that the permeability is governed by cell size and the flow inertia parameter is governed by cell size, tortuosity and a roughness parameter. It is concluded from data obtained from crushed and uncrushed foams that the roughness parameter is strongly associated with cell membrane density. It is proposed that the experimental procedure can be used to quantify separately the effects of cell size and cell membranes. (Author abstract) 5 refs.

**083706 CARBIDE INTRODUCES NON-FLUOROCARBON FLEXIBLE URETHANE FOAM CHEMISTRY SYSTEM.** Union Carbide has introduced a new chemistry system for flexible polyurethane foam that can produce a wide variety of polyurethane foam grades without the use of chlorofluorocarbons (CFCs). The company claims it also offers improved performance in furniture, mattress, and automotive uses. The new Ultracel Intermediates are used to produce flexible foams that can be manufactured without the use of any auxiliary blowing agent such as CFCs or methylene chloride, the flexible foam industry's other key auxiliary blowing agent. Methylene chloride is under scrutiny as a suspected carcinogen. These foams also offer increased support, comfort, and durability over conventional grades of urethane foam commonly used in home furnishings.

**Glass Transition** See POLYURETHANES—Thermal Properties.

**Injection Molding**

**083709 EQUIPMENT FOR THE MANUFACTURE OF DENSE POLYURETHANE PRODUCTS.** Equipment has been developed, including equipment for heating raw materials, low-pressure molding equipment with an output of 0.2 to 10 kg/min for one- and two-stage fabrication of products made from polyurethane and based on polyethers and polyesters, and equipment for vulcanizing and hardening the products. The molding equipment consists of the following: units for storing the components; batching and mixing systems; units for degasification and drying; systems for thermostating and process control. The output of the molding equipment and the quality of the products very much depends on the efficiency of the processes of degasification, drying, batching, and mixing. Two types of rotary vulcanizers were developed for products of different weight. Both vulcanizers are in the form of a flat circular platform which is rotated by means of an electric motor. 3 refs.

**Ionic Conduction**

**083710 ION CONDUCTIVITY OF POLY(ETHYLENE OXIDE)-BASED POLYURETHANE NETWORKS CONTAINING ALKALI METAL SALTS.** Ion conductivity of poly(ethylene oxide) (PEO)-based polyurethane networks containing alkali metal salts has been investigated. Consequently, it has been revealed that the conductivity is dependent on the following parameters: lattice energy of the alkali metal salt, concentration of alkali metal salt, and the cross-linking density of the network polymer (which is a function both of the amount of cross-linking agent and the molecular weight of PEO). Under optimal conditions, the conductivity at ambient temperature corresponded to  $2.51 \times 10^{-5} \text{ Scm}^{-1}$ , which is greater than that of a typical alkali metal-PEO system by a factor of about  $10^2$  to  $10^3$ . Moreover, from the standpoint of the application to electrochromic displays (ECD), tensile bond strength between the polymer electrolytes and tungsten trioxide ( $\text{WO}_3$ ), which is the most promising electrochromic material, has been evaluated.

The bonding strength of the bond of  $WO_3$  with the present electrolyte has been found to be much larger than that of the alkali metal-PEO system. (Author abstract) 18 refs.

**083711 NEW NON-TOXIC REPLACEMENT FOR METHYLENE-BIS-o-CHLOROANILINE (MBOCA)-4,4'-METHYLENE-BIS-(3-CHLORO-2,6-DIETHYLANILINE)-(MCDEA).** The manufacture of polyurethanes using an aromatic diamine as a chain-extender or cross-linking agent is widely practiced. Although primary and secondary polyamines have been used, aromatic diamines and in particular 4,4'-methylene-bis-2-chloroaniline (MBOCA) are the most extensively used. With the use of MBOCA, it was possible to manufacture urethane elastomers with particularly good mechanical properties and with acceptable processing times. In general, many of the typical polyurethane elastomer formulations were tried, albeit on a small scale, but the products tended to work more or less as chain-linkers or cross-linkers for the elastomer systems. Three polymer systems were used for the comparative evaluation of these new chain extenders. 9 refs.

Voelker, Th. (Lonza Ltd, Basel, Switz); Balling, Peter. *J Elastomers Plast v 19 n 3 Jul 1987 p 219-230*.

**083712 FATE OF TDI AND MDI IN AIR, SOIL, AND WATER.** Toluene diisocyanate (TDI) and methylene diphenylene diisocyanate (MDI) are used in the production of polyurethanes. The International Isocyanate Institute, Inc. has sponsored a range of studies to determine the fate of TDI and MDI in air, soil and water. Studies of simulated atmospheric conditions indicate that TDI is destroyed predominantly by OH radicals, without the formation of toluene diamine (TDA). TDA or MDA (methylene dianiline), if generated in the atmosphere from any source, are also destroyed by OH radical attack, and no accumulation of these products is expected. In soil and water TDI and MDI are converted to polyureas, which are chemically inert, and which appear to cause no toxicological effects. (Edited author abstract) 36 refs.

**083713 DYNAMIC MECHANICAL BEHAVIOR AND STRUCTURE OF POLYURETHANEIMIDES.** Dynamic mechanical behavior and X-ray diffraction of two series of segmented polyurethaneimides (PUI) prepared either from poly(ethylene adipate) glycol (PEA), pyromellitic dianhydride (PMDA) and 4,4'-diphenylmethane diisocyanate (MDI), or from PEA, PMDA, and a mixture of 2,4- and 2,6-tolylene diisocyanate (TDI) were studied. All samples have a two-phase structure of the soft polyester (PE) phase and hard polyimide (PI) phase. PI microdomains containing MDI units are semicrystalline, whereas those with TDI are crystalline only at highest contents of TDI. The storage modulus  $E'$  increases with increasing fraction of the hard phase. The MDI-containing hard phase has a stronger effect on  $E'$  and also makes the plateau on the dependence of  $E'$  on temperature more pronounced. (Author abstract) 13 refs.

**083714 EFFECT OF IONIC BONDING ON THE CONCENTRATION OF EFFECTIVE NETWORK CHAINS IN CROSSLINKED POLYURETHANE IONENES.** The phase separated structures of crosslinked polyurethane ionenes with different lengths of ionic segments were studied. The contributions of ionic bonds in the concentration of effective network chains,  $v_e/V$ , which were estimated from stress-strain measurements,

were separated from those of covalent bonds. A relation between the primary  $v_e/V$  and the degree of phase separation estimated from dynamic mechanical measurements was noticed. As the degree of phase separation increased, the primary  $v_e/V$  decreased in DBH series and increased in XDC series. These different trends in the primary  $v_e/V$  arise from the different sizes of ionic domains in the two series of polyurethane ionenes. (Edited author abstract) In Japanese. 6 refs.

**083715 WPLYW WILGOCI NA WLASCIWOSCI TERMOPLASTYCZNYCH ELASTOMEROW URETANOWYCH W STANIE STOPIONYM.** [Effect of Moisture on the Properties of Thermoplastic Urethane Elastomers in Molten State]. The effect of water content on the degradation of thermoplastic urethane elastomers in molten state has been investigated. It has been found that humidity adsorbed by the granulate used in the injection molding catalytically accelerates polymer decomposition and considerably decreases its rheothermal stability, melt viscosity, molecular mass and deteriorates the mechanical properties of the product. It has been established that a safe processing of molten elastomers is possible, if water content of the granulate used for injection molding does not exceed 0.05% by weight. (Author abstract) In Polish. 18 refs.

**083716 SUBSTRATE DEFORMATION STUDIES BY PHOTOELASTICITY IN SINGLE PARTICLE IMPACTS.** Dynamic photoelasticity methods have been used to study the substrate deformation in polyurethane rubber due to the impact of a 3 mm steel ball with a velocity of 50 m/s and at angles of 30° and 90°. The experimental set-up used a multiple-spark camera with an integral polariscope to visualize the dynamic stress field generated by the impact. The stress fields were photographed both in the plane of the impact as well as below it. The analysis of the data showed that the rate of propagation of the stress field was 198 m/s. A maximum strain rate of  $2.86 \times 10^3$  m/s was determined after a small time following the impact which also coincided with the time of maximum indentation. (Author abstract) 8 refs.

**083717 MECHANICAL PROPERTY AND MORPHOLOGY OF POLYURETHANE-POLYACRYLONITRILE BLEND SYSTEM - A MECHANICAL MODEL INVESTIGATION.** In this paper, the mechanical property and morphology of a polyurethane-polyacrylonitrile blend system has been studied. A mechanical model with an empirical distribution function of volume fraction has been proposed. The distribution function is interpreted in terms of the blend morphology. The modulus composition relationship of the blend system can be described satisfactorily by our generalized parallel model. The interaction parameter has been calculated from the model parameters, which is well consistent with our another investigation on the PU-PAN blend system. (Author abstract). 16 Refs.

**083720 POLYISOCYANURATE THERMOSET FOR STRUCTURAL RIM APPLICATIONS.** Polyisocyanurate modified polyurethanes have been recently used with preplaced mat reinforcement for structural RIM applications. However, some of the flow characteristics and the thermal properties of these systems resemble those of polyurethanes. ARCO Chemical has been active in developing a mat reinforced RIM system based upon a modified polyisocyanurate thermoset. This new system combines the excellent properties of thermal, chemical resistance associated with polyisocyanurates with a good balance of physical properties, low viscosities, excellent electrical properties and a good adhesion to reinforcing agents. This paper will discuss the chemistry and the properties of the system along with its application in the electronic and automotive industries and in markets currently served by epoxy resins. (Edited author abstract)

2195-2199.

**083723 MORPHOLOGY AND MECHANICAL PROPERTIES OF CROSSLINKED POLYURETHANE IONENES.** Crosslinked polyurethane ionenes with different lengths of ionene segments were prepared by using poly(oxytetramethylene) glycol ( $M_n=984$  and 2040) and 4,4'-diphenylmethane diisocyanate as starting materials. The morphology and mechanical properties were studied. The equimolar reaction of the isocyanate-terminated prepolymer with 2-dimethylaminoethanol in DMF yielded a multifunctional amino-terminated prepolymer containing isocyanurate groups as branching points. Therefore, the crosslinked polyurethane ionenes were obtained by the reaction of the amino-terminated prepolymers with dihalides: p-xylylenedichloride (XDC) and 1,6-dibromohexane (DBH). The ionene segment length was varied by adding N,N,N',N'-teramethylhexanediamine. (Edited author abstract) In Japanese. 8 refs.

Sasaki, Nobuyoshi (Kinki Univ, Iizuka, Jpn); Yokoyama, Tetsuo. *Kobunshi Ronbunshu* v 19 n 4 1987 p 857-865.

**083724 MORPHOLOGY OF BLOCK COPOLYURETHANES. III. EFFECT OF POLYETHER MOLECULAR WEIGHT ON THE MECHANICAL PROPERTIES OF SOLVENT CAST FILMS.** A homologous series of copolyether-urethane-ureas were synthesized with polypropylene glycol segments having molecular weights of approximately 200, 400, 700, 1000, 2000, and 3000. These copolymers were characterized using tensile measurements and dynamic mechanical spectroscopy. The dynamic mechanical measurements at low frequencies showed evidence of the existence of an  $\alpha$ -relaxation process. This was attributed to constrained polyether segments located at the interfacial region between the hard urea segments and the soft polypropylene glycol segments. (Edited author abstract) 10 refs.

## Photolysis

**083725 EFFECT OF CRYSTALLINITY AND FLEXIBILITY ON THE PHOTODEGRADATION OF POLYURETHANES.** Using fluorescence spectroscopy and gel content measurement, the photolysis of simple polyurethanes based on methylene 4,4'-diphenyl-diisocyanate (MDI) is shown to depend on both the flexibility and crystallinity of the polymer. Polyurethane films based on MDI and 1,12-dodecanediol (MDI-12) can be either annealed or quenched to yield a semicrystalline (as measured by DSC and X-ray diffraction) or amorphous film, respectively. In the case of the quenched film, photolysis yields an ortho photo-Fries product whereas the annealed film does not. Similarly, for a given photolysis time the annealed film generates a lower extent of crosslinked gel. In addition, photolysis of amorphous polyurethane films derived from MDI and ethylene oxide oligomers shows that for relatively inflexible polymers with only three ethylene oxide segments, little or no ortho photo-Fries rearrangement products are generated upon photolysis. (Edited author abstract) 18 refs.

Hoyle, Charles E. (Univ of Southern Mississippi, Hattiesburg, MS, USA); Kim, Kyu-Jun. *J Polym Sci Part A* v 25 n 10 Oct 1987 p 2631-2642.

**083726 EFFECT OF FLEXIBILITY ON THE PHOTODEGRADATION OF AROMATIC DIISOCYANATE-BASED POLYURETHANES.** The photolytic degradation of 2,4-TDI/aliphatic diol polyurethanes is directly dependent on the flexibility of the polymer backbone. The extent of photodegradation is accelerated above the glass transition temperature, indicating the role of chain flexibility and/or oxygen diffusion in the decomposition process. Photolysis of the model compound ethyl N-phenylcarbamate in neutral host polymer matrices indicates that the para photo-Fries to ortho photo-Fries product ratio experiences an accelerated increase with temperature above the glass transition of the polymer

matrix. (Edited author abstract) 23 refs.

**083727 WHAT POLYURETHANE? WHERE?** The chemical term polyurethane can apply to many different kinds of materials. There are the castable elastomers, which are the materials of primary importance in this discussion. There are foams, both rigid and flexible types. Rigid foams are used for applications such as insulation while flexible foams are used in upholstery and cushioning. These are each very large markets. Thermoplastic urethanes are materials which are fully reacted and processed by a melting and extrusion or injection molding procedure. Millable gums are handled in very much the same way as conventional rubber, that is, they are compounded with fillers and other ingredients, are processed on rubber machinery and are cured by vulcanization processes with peroxides or, in some cases, with sulfur. In this way the unique properties of urethanes can be achieved by the same methods used to process conventional rubbers. So what is essential, in terms of applications engineering, is to appraise each and then to select the particular polyurethane that meets the criteria of both economics and performance.

Fuest, Ronald W. (Uniroyal Chemical Co). *Rubber World* v 196 n 6 Sep 1987 p 21-22, 24-25, 50.

**083728 THERMAL AND DYNAMIC MECHANICAL PROPERTIES OF POLYURETHANEUREAS.** Measurements were made of the thermal and dynamic mechanical properties of 22 polyurethaneureas of varying diol molecular weight, type of aromatic chain extender, diol molecular weight distribution, and chain extender stoichiometry. The dynamic mechanical data, obtained as a function of temperature and frequency (in the kHz region), were used to construct master curves of shear modulus and loss factor over a wide range of reduced frequencies. Soft segment crystallization occurs at the higher diol molecular weights. Dynamic mechanical properties are well correlated with the soft segment glass transition. Diol molecular weight influences dynamic mechanical properties by affecting the degree of phase separation and hence glass transition temperature. (Edited author abstract) 15 refs.

**083729 POLYURETHANE AND POLYISOCYANURATE RIGID BOARDSTOCK TECHNOLOGIES.** Given the global nature of urethane technology and markets, it is somewhat surprising that there exist such wide technology differences between the United States and European rigid boardstock industries. Catalyst technologies dramatically shifted as the U.S. industry incorporated aromatic polyester polyols at increasingly high levels. This paper will explore in detail, both from a marketing and technology perspective, the major factors which have contributed to this universal acceptance of these systems in the U.S. The situation in Europe is quite different; although aromatic polyester polyols are becoming more readily available, they still have not gained a significant penetration in the European market. (Edited author abstract)

**083730 POLYURETHANE CATIONOMERS. I. STRUCTURE-PROPERTIES RELATIONSHIPS.** Polyurethane (PU) cationomers have been synthesized by quaternizing tertiary amine-containing linear polyurethanes using different quaternizers containing acid groups.

The effect of chemical structure of PU cationomers on the physical properties was studied. The mechanical properties of PU cationomers were improved by decreasing the molecular weight of poly(caprolactone) glycol, and increasing concentration of quaternary ammonium. Decreasing the carbon number in the alkyl group of the N-alkyl diethanol-amine chain-extenders, and using rigid symmetrical diisocyanates, improved the mechanical properties of the PU cationomers. The effects of these factors on the glass transition temperature of PU cationomers were also examined. The mechanical properties of the PU cationomers deteriorated when immersed in water and recovered after removal of the water. (Edited author abstract) 24 refs.

Al-Salah, H.A. (Univ of Detroit, Detroit, MI, USA); Xiao, H.X.; McLean, J.A. Jr.; Frisch, K.C. *J Polym Sci Part A* v 26 n 6 Jun 1988 p 1609-1620.

**083731 <sup>13</sup>C NMR OF POLYURETHANE IN THE SOLID STATE.** <sup>13</sup>C NMR spectra of bulk polyurethane samples are reported. Polyurethanes are block copolymers composed of hard and soft segments which often undergo microphase separation with the resultant formation of hard and soft domains. The hard domain component can be observed selectively by using high-power proton decoupling, cross polarization and magic angle spinning (MAS). The soft domain component can be observed selectively by using low-power proton decoupling and MAS. The <sup>13</sup>C NMR results show that one polyurethane sample has hard domains which are composed of hard segments, but the other sample does not have any hard domains. To confirm the <sup>13</sup>C NMR results, the morphology and properties of these samples were investigated by DSC, dynamic mechanical properties, stress-strain properties, pulsed NMR, WAXS, polarizing microscopy and TEM. (Edited author abstract) 10 refs. In Japanese.

## Processing

**083732 4,4'-METHYLENE-BIS(3-CHLORO-2,6-DIETHYLANILINE)-M-CDEA - A NEW CHAIN-EXTENDING AGENT FOR CAST PU-ELASTOMERS.** First developments of the use of 4,4'-Methylenebis-(3-chloro-2, 6-diethylaniline), abbreviated to M-CDEA, as a chain-extending agent were reported in October, 1986. In the current paper, the authors present a series of new findings on the relationship between the structure of this hexa-substituted methylene-bis-aniline and its effectiveness as a chain-extending agent for various cast PUR elastomers. Also discussed is information on the reactivity of M-CDEA, and on the visual, physical and in particular on dynamic properties of end products derived from M-CDEA. The presentation compares CDEA with commercially available amines used as curatives. (Author abstract) 9 refs.

## Production

**083733 POLYURETHANES (PUR).** Since their discovery fifty years ago, polyurethanes have clearly demonstrated their versatility and ability to stimulate new areas of demand. Today, despite more modest growth prospects, the polyurethane industry is continuing the process of innovation both in terms of technology and markets. Following the outlook for polyurethanes by major segment, assess developments and implications in terms of polyurethane raw materials is reviewed and the structural changes which are taking place in the industry is described.

**083735 AROMATIC DIOLS AS CHAIN EXTENDER IN PU REACTION MOLDING.** Polyurethane (PU) has outstanding properties, and has been applied in many fields. In general, it is prepared by the reaction of diisocyanate, polyol, chain extender, surfactant, catalyst, filler, reinforcement and blowing agent, etc. Most studies are based on the use of aliphatic chain extender such as 1,4-butanediol. The disadvantage is their low sag temperature. In this study, the aromatic diols such as bis(hydroxyethyl) terephthalate, bisphenol A and hydroquinone are used to replace aliphatic diols commonly used in the conventional PU recipe. Thus, formed products are characterized and their mechanical and thermal properties are investigated. Results show that the products have the better mechanical property and the outstanding thermal resistant property. (Edited author abstract) 6 refs.

**083737 POLYUREA HERALDS LATEST GENERATION OF RIM SYSTEMS.** Polyureas have been well known for years, but they are only now making their bid for recognition and acceptance as RIM (reaction injection molding) materials. Grades with a virtually limitless degree of versatility can be formulated, from soft elastomers to stiff, hard elastoplastics. Polyurea systems consist of polyether polyamines, diamine chain extenders such as DETDA, and MDI-based isocyanates. Note that polyurea RIM technology uses polyether polyamines instead of polyether polyols, and no catalysts. The implications of these two differences are discussed.

**083738 RIM STRUCTURAL FOAMS IN THE EUROPEAN BUILDING INDUSTRY.** Since their introduction 18 years ago, building elements made of polyurethane RIM materials have been a great success in the European building industry. One of the main features of polyurethane reaction mixes as their excellent adhesion to a wide variety of materials like aluminum, steel, wood, and glass fiber reinforced plastics. This feature yields composite articles of two basic types. Polyurethane RIM materials are available in three basic types, with marked differences in their density and hardness. Two of the three types are reviewed in this paper.

Knipp, Ulrich (Bayer AG, Leverkusen, West Ger). *J Cell Plast* v 23 n 6 Nov-Dec 1987 p 540-554.

**083739 APPLICATION OF THERMAL METHODS IN THE CHARACTERIZATION OF POLY(URETHANE-UREA)S FORMED BY REACTION INJECTION MOULDING.** Differential scanning calorimetry (DSC) and dynamic mechanical thermal analysis

(DMTA) have been used in conjunction with tensile testing and transmission electron microscopy (TEM) to characterize novel segmented poly(urethane-urea) (PUU) network materials formed by reaction injection molding (RIM). The materials ranged from tough translucent elastomers to opaque brittle plastics depending on the chemical nature and weight fraction of the hard segments (HS). DSC and DMTA studies showed the PUU materials to be phase-separated; this was confirmed by TEM and tensile testing. (Edited author abstract) 16 refs.

**083741 PRIM: EXPERIMENTAL STUDIES OF FLOW TRANSIENTS IN MIXHEADS.** The flow of polyol-glass fiber slurries and polymeric isocyanate reactants for polyurethane reinforced reaction injection molding (PRIM) has been studied under process conditions in high flow rate recirculation and static pre-pressurization mixheads, using a two stream computer controlled PRIM machine. Particular attention has been paid to sequence control in each mixhead and associated pressure transients at the start of the injection period. (Edited author abstract) 14 refs.

Coates, P.D. (Univ of Bradford, Bradford, Engl); Sivakumar, A.I.; Johnson, A.F. *Plast Rubber Process Appl* v 8 n 4 1987 p 203-213.

**083742 PRODUCTION, PROPERTIES, AND APPLICATION OF POLYURETHANE RRIM.** The production of automotive exterior body panels in the PUR-RRIM process is a comparatively new technology. For a better acceptance of RRIM moldings, cost reductions in the production process are necessary which, in turn, require noticeable progress in the material and process development. Due to the improvements made in the field of both raw materials and production units, the PUR-RRIM process has, in the last few years, become interesting also for high-volume production. A handicap in this connection is that the development of the RRIM process is, to a large extent, based on the practical experience of a few experts. A discussion is presented of problems relative to high-volume production. (Edited author abstract)

Braun, H.-J. (Inst for Polymer Testing & Polymer Science, Stuttgart, West Ger); Eyerer, P.; Frank, U.; Huettner, M.; Ludwig, H.-J.; Wurster, T. *Adv Polym Technol* v 8 n 1 1988 p 17-26.

**083743 IN-MOLD BONDING EXPANDS RIM'S VERSATILITY.** The ability of reaction injection molding (RIM) urethanes to exhibit high elongation and resilience, while retaining high modulus, makes them suited to a wide variety of applications. RIM's popularity is also in its rapid molding cycle, which permits high output rates to be achieved. RIM's growth has also been the recent ability to bond urethane to materials inserted in the mold such as glass, mounting plates, reinforcement members and metal parts. Recently, these new RIM urethane adhesives played an integral role in the development and success of modular, RIM-encapsulated stationary automobile windows.

**083744 MOLDABILITY DIAGRAMS FOR THE REACTION INJECTION MOLDING OF A POLYURETHANE CROSSLINKING SYSTEM.** Moldability diagrams for the filling and curing stages of a RIM process are obtained based on a simplified engineering approach. The key process parameters chosen for the filling stage are initial material temperature and filling time. In the curing stage, the critical parameters are considered to be mold wall temperature and demold time. Experimental results obtained on a laboratory-scale RIM machine on a crosslinking polyurethane system are used to check the validity of the predicted molding areas. The agreement obtained is satisfactory considering the broad range of processing parameters used. (Edited author abstract) 28 refs.

**Reaction Kinetics** See POLYMERS—Reaction Kinetics.

**Rheology**

**083745 STOICHIOMETRY EFFECTS ON RHEOLOGY OF MODEL POLYURETHANES AT THE GEL POINT.** In this study the rheological behavior of PU gels with unbalanced stoichiometry is investigated. The variations of the two material parameters in eq 1, S and n, are followed over the entire range of stoichiometric ratios for which gelation can take place. The evolution of the rheological behavior at the GP as a function of the stoichiometric ratio,  $0.5 < r < 2$ , is presented. The authors emphasize that the results apply at the gel point of model cross-linking polymers at temperatures far above vitrification. The prepolymers consisted of large bifunctional molecules, however, with an initial molecular weight well below the critical mass for entanglements, and of small trifunctional cross-linker molecules. 21 refs.

**083747 SIMS AND XPS STUDIES OF POLYURETHANE SURFACES: 2. POLYURETHANES WITH FLUORINATED CHAIN EXTENDERS.** A series of fluorine-containing segmented poly(ether urethanes) and poly(ether urethane ureas), previously characterized by angular dependent x-ray photoelectron spectroscopy (XPS) have been re-examined using static secondary ion mass spectroscopy (SIMS). Comparison of the data from the two techniques has shown that the intensity of secondary ion signals which characterize the hard and soft segments can be used quantitatively for direct analysis of the molecular composition at the surface. Moreover, the SIMS sampling depth for the conditions used has been shown to be approximately 10 Å, significantly less than

the XPS sampling depth under normal conditions, and similar to the XPS sampling depth at high glancing take-off angle (with respect to the surface normal). (Author abstract) 16 refs.

**083748 INFRARED SPECTROSCOPY AND X-RAY STUDIES OF MODEL ALIPHATIC URETHANES.** Based on the identity of the IR spectra of crystalline aliphatic polyurethanes and low MW diurethanes, the latter were chosen as models for fragments of the polymer chain. A full X-ray structural study was made of hexamethylene-1, 6-bis-decylurethane and of hexamethylene-1, 6-bis-ethylurethane. The relationship of the bands in the IR spectra of the polyurethanes was defined more precisely. (Author abstract) 10 refs.

**083749 QUANTITATIVE DETERMINATION OF ABSORBED WATER IN CO(POLYETHER) POLYURETHANE MEMBRANES USING FT-IR/ATR.** The authors used attenuated total reflectance FT-IR spectroscopy to quantitatively correlate absorbed water in a series of membranes with band area, following appropriate subtraction and normalization. The FT-IR data were compared with data obtained gravimetrically. The membrane series studied consisted of co(polyether) polyurethane polymers synthesized from hydrophilic polyethylene glycol (PEG) 600, 1000, or 1540 blocks and hydrophobic urethane segments. In addition to providing information about water content of membranes, the spectra also yield information which permits some conclusions to be drawn concerning the nature of the water absorbed in the polymers. 15 refs.

## Spectrum Analysis

**083750 INFRARED SPECTRAL STUDY ON THE HEAT CURING REACTION OF GLYCERIN-TERMINATED URETHANE PREPOLYMERS.** Glycerin, toluene diisocyanate (TDI), and polyglycol (PG) were reacted at various molar ratios to produce glycerin-terminated urethane prepolymers of different molecular weights. The prepolymers were mixed with equivalent phenol-blocked trimethylol propane-TDI-urethane triisocyanate in m-cresol to give a coating solution. The solution was coated and baked to give polyurethane crosslinked films. The changes of the functional groups during the crosslinking reaction and the mechanical properties of the polyurethane crosslinked films were studied. (Edited author abstract) 6 refs.

**Structure** See Also BLOCK COPOLYMERS—X-Ray Analysis.

**083751 DETERMINATION OF THE STRUCTURE AND COMPOSITION OF CLINICALLY IMPORTANT POLYURETHANES BY MASS SPECTROMETRIC TECHNIQUES.** Curie-point pyrolysis mass spectrometry (Py-MS) and direct probe pyrolysis high resolution mass spectrometry (Py-HRMS) were used to identify the components and additives used in the synthesis and compounding of Biomer, Lycra Spandex, Tecoflex, and Pellethane. Two types of Biomer were identified (P and Q, our notation) which are composed of poly(tetramethylene glycol) (PTMG) capped with 4,4'-methylenebis(phenylisocyanate) (MDI) and chain-extended with ethylenediamine (EDA). Both forms contain

4,4'-butylidene-bis-(6-t-butyl-m-cresol) antioxidant, and Biomer Q also contains an additive which appears to be a quaternary ammonium chloride salt. Lycra Spandex was found to be identical to Biomer Q, with the exception that a low molecular weight polydimethylsiloxane oil is also present. Tecoflex (type SG80A) is composed of PTMG capped with 4,4'-diisocyanatodicyclohexylmethane and extended with 1,4-butanediol (BD). An industrial grade and a medical grade of Pellethane were analyzed. Both were composed of PTMG capped with MDI and extended with 1,4-butanediol. The industrial grade also contains an antioxidant, possibly butylated diphenylamine. (Edited author abstract) 18 refs.

**083752 INITIATION OF MICROPHASE SEPARATION IN SEGMENTED POLYURETHANES/EMICARBAZIDES.** An investigation has been made of ionometric polyurethanes/emicarbazides containing quaternary halide (Cl, Br, I) pyridinium salts, used as chain elongators of the rigid blocks. It has been shown by use of a number of methods (low-angle X-ray diffraction, DSC etc.) that the polarity and electronegativity of the counter-ion is the predominant part in the processes of microphase separation and, consequently, in determining the properties of this series of polymers. A formula to determine the degree of heterogeneity of the segmented polyurethanes is put forward on the basis of the results obtained by differential scanning calorimetry. (Edited author abstract) 20 refs.

**083753 STRUCTURE AND MORPHOLOGY OF SEGMENTED POLYURETHANES: 4. DOMAIN STRUCTURES OF DIFFERENT SCALES AND THE COMPOSITION HETEROGENEITY OF THE POLYMERS.** The morphology of polybutadiene containing polyurethanes has been studied by using small-angle light scattering (SALS), small-angle X-ray scattering (SAXS), phase contrast microscopy and electron microscopy. Domain structures having sizes of 1000, 100 and 10 nm are observed within these samples and are explained as the results of segregation on the molecular level, subchain level and segmental level, respectively. These phenomena are related to the molecular heterogeneity in chemical composition and average hard segment length. It has been found that because of the analogy in molecular structure with SBS block copolymers, segmented polyurethanes may form microdomains of soft and hard segments with more or less uniform size and regular arrangements in space. (Author abstract) 26 refs.

**083754 STRUCTURE OF SUCCESSIVELY CURED INTERPENETRATING POLYMER NETWORKS IN RELATION TO THE CROSSLINK DENSITY OF THE PENETRATING COMPONENT.** Structural features of successively cured interpenetrating networks composed of polyurethane (PU) and of poly (methyl methacrylate) (PMMA) of varying crosslink density were studied by wide-angle and small-angle X-ray methods. It was found that the degree of phase separation of the studied network components is largely determined by the crosslink density of the penetrating component. An increase in the crosslink density of the penetrating network leads to increased incompatibility, but a sharp decrease in the mobility of the more strongly branched segments of the network structure increases the probability of entanglements between the fragments of the matrix and of the penetrating network, resulting in the persistence of a certain degree of PU and PMMA chain interpenetration in the resulting material. (Author abstract) 12 refs.

**083755 ASPECTS OF THE EFFECT OF AEROSIL ON THE STRUCTURE AND PROPERTIES OF FILLED NETWORK POLYURETHANES.** The structure and properties of network PUs based on polyoxypropylene glycol, trimethylolpropane and toluylene-2,4- or diphenylmethane-4,4'-diisocyanate cured in presence of different amounts of Aerosil have been studied. The possibility of evaluating the contribution of the two types of specific bonds to the network structure of filled PUs is demonstrated. Aerosil has a fundamentally different influence on the formation of the network structure of polymers obtained from diisocyanates of symmetrical and non-symmetrical structure, reflected in the values of the effective density of the PU cross link. (Author abstract). 18 Refs.

**083757 EFFECTS OF DIFFERENT POLYOL-TERMINATED URETHANE PREPOLYMERS ON THE PROPERTIES OF THEIR CORRESPONDING CROSSLINKED FILMS.** Polyglycols (PG) and toluene diisocyanate (TDI) were reacted at various molar ratios to produce isocyanate-terminated polyurethanes and were then reacted with glycerine, pentaerythritol (PE), or trimethylol propane (TMP) to produce hydroxyl-terminated urethane prepolymers of different molecular weights. These prepolymers were mixed with an equivalent amount of blocked isocyanate in a mixture of m-cresol and naphtha to give the varnishes. Pretreated copper wires were coated and baked to give polyurethane coated magnet wires. The mechanical properties of the polyurethane crosslinked films, the change of functional groups during the crosslinking reaction, and the properties of magnet wires coated with polyurethane varnishes are discussed. (Author abstract) 23 refs.

**083760 SYNTHESIS OF POLYURETHANES CONTAINING NUCLEIC ACID BASE DERIVATIVES AS GRAFTED PENDANTS AND THEIR PRECURSOR AMINO FUNCTIONALIZED POLYURETHANE.** A new route to polyurethanes containing nucleic acid base derivatives as grafted pendants have been established. The method is based on the grafting of 2-(thymine-1-yl)propionic acid (TPA) or 2-(adenine-9-yl)propionic acid (APA), onto amino functionalized polyurethane, poly[2-amino-2-methyl-1,3-propylene methylene bis(4-phenyl carbamate)] (PU-NH<sub>2</sub>, IX) at the primary amino group by the N-hydroxy compound of active ester technique. Two novel polymer models of polynucleic acid - poly[2-(2'-(thymine-1'-yl)propionamide)-2-methyl-1,3-propylene methylene bis(4-phenyl carbamate)] (PU-NHT, X) and poly[2-(2'-(adenine-9'-yl)propionamide)-2-methyl-1,3-propylene methylene bis(4-phenyl carbamate)] (PU-NHA-40, XI) - were obtained. Prior to polymer synthesis, the amidation of APA with 3-aminoheptane or diethylamine were carried out as a model reaction study and the related monomer model compounds were prepared by the same methods. (Edited author abstract) 17 refs.

**083761 POLYESTER POLYOLS FOR POLYURETHANES FROM PET WASTE: KINETICS OF POLYCONDENSATION.** The kinetics of polyesterification of the glycolized PET waste with adipic acid is reported. Glycolysis of PET waste was carried out with ethylene glycol at three different ratios of PET waste to glycol. The glycolized products could be readily polyesterified by reacting with adipic acid, to give polyester polyols with low acid number. The kinetic results of the polyesterification of glycolized PET waste are compared to the polyesterification of pur diols, namely ethylene glycol and bis(hydroxyethyl) terephthalate (BHET) with adipic acid. The reactions follow second-order kinetics at 170°C and the rate of polyesterification of the mixed diol system from PET waste lies intermediate between those of the pure diols, namely, EG and BHET. Ethylene glycol exhibited the highest reactivity. At 200°C the kinetic plots of the mixed diols from PET waste were nonlinear, and thus the reaction may not follow second-order kinetics. The nonlinearity is explained in terms of the different reactivities of the different diol species in the reaction mixture. The polyester polyols, when cured with polymeric 4,4'-diphenyl methane diisocyanates, gave polyurethane rigid foams and elastomers. (Edited author abstract) 7 refs.

**083762 INTERPENETRATING POLYMER NETWORKS BASED ON CASTOR OIL IX.** Crosslinked polyurethane were obtained when trifunctional -OH group containing castor oil was reacted with difunctional toluene-2,4-diisocyanate under different stoichiometric conditions varying NCO/OH ratio. These polyurethanes swelled in n-butyl acrylate monomer and subsequently polymerized by radical polymerization initiated with benzoyl peroxide in presence of crosslinking agent ethylene glycol dimethacrylate. A series of interpenetrating networks, PU/PnBA IPNs, were obtained as tough films by transfer molding. All these IPNs films were characterized by resistance to chemical reagents, thermal behavior (DSC, TG), and mechanical studies such as tensile strength, Young's modulus, elongation at break (%) and hardness shore A. (Edited author abstract) 31 refs.

Thermal Insulation

**083764 COMPARATIVE EVALUATION OF THE HEAT RESISTANCE OF POLYURETHANE COMPOUNDS.** Here we record an investigation of the thermal characteristics and heat resistance of type VILAD-13-1 and VILAD-14 polyurethane compounds and the influence of modification of VILAD-13-1 compound on the dielectric characteristics under long-term thermal aging. Types VILAD-13-1 and VILAD-14 compounds are made up of two components, a polyol (component A) and polyisocyanate (component B). At room temperatures both components are in the liquid state. The differences between one compound and another are occasioned by the utilization of different polyols. (Author abstract) 2 refs.

Thermal Properties

**083765 THERMAL BEHAVIOR OF CAST POLYURETHANE ELASTOMERS.** Thermal properties like glass transition temperature, initial decomposition temperature, integral procedural decomposition temperature, and temperature at various % weight loss of a number of polyurethane systems are reported in this paper. Glass transition temperature was determined on TMA, and other thermal properties were determined by thermogravimetry. The experiments were designed to understand various factors such as length of chain extender moiety, flexibility of chain extender units by substitution of ether link in the diol chain, nature of bonds (unsaturation) in the extender unit, and nature of diisocyanates. (Edited author abstract) 14 refs.

Viscoelasticity

**083766 INFLUENCE OF CHEMICAL STRUCTURES OF POLYURETHANE RESINS MOLDED BY REACTION INJECTION MOLDING ON VISCOELASTIC PROPERTIES AT HIGH FREQUENCIES.** Dynamic viscoelastic properties of polyurethane resins molded by reaction injection molding (RIM) have been examined by forced oscillation method at 2 approximately 500 Hz. Polyurethane raw materials are aliphatic and aromatic polyols which have several mol numbers of PO (propylene oxide) adducts, and P-MDI (polymeric diphenyl methane diisocyanate). Increasing crosslinking density and adding benzene rings to polyols are effective ways to raise the  $T_g$  of polyurethane resins molded by RIM. Increasing crosslinking density could be obtained by decreasing mol numbers of PO adducts or by increasing functionalities of polyol. (Edited author abstract) In Japanese. 19 refs.

Waste Utilization

**083767 POLYOL RECOVERY FROM ELASTOMER POLYURETHANE WASTE.** Waste and scraps, from polyurethane elastomers, mainly from the shoe sole production, can be conveniently converted by a transesterification process into polyols which can be reused in the production of rigid foams, with both economical and ecological advantages. In the transesterification process, secondary reactions leading to amine formation, can be controlled by means of the reaction conditions. In the production of rigid foam the recovered products are mixed with fresh polyol; the recovered/fresh polyol ratio must be moderate in order to obtain materials with sufficiently high dimensional properties. (Author abstract) 14 refs.

Simioni, F. (Univ di Padova, Padua, Italy); Modesti, M.; Rienzi, S.A. *Cell Polym* v 6 n 6 1987 p 27-41.

Wear

**083768 ROLE OF STRUCTURE FACTOR IN EVALUATING POLYURETHANE WEAR RESISTANCE.** We present the results of studies of the wear resistance of linear and sterically structured polyurethanes (PU) as a function of the ratio of the basic components in the synthesis stage and their chemical structure. It is established experimentally that the rigid block content in the molecule or in the interstitial fragment has significant influence on PU wear resistance. These studies permit a rational approach to regulation of the tribotechnical properties of polyurethane systems. (Author abstract) 12 refs.

**083770 DEFECT DIFFUSION MODEL FOR VOLUME AND ENTHALPY RECOVERY IN AMORPHOUS POLYMERS.** Glasses are known to undergo spontaneous densification during isothermal annealing. This volume recovery process, which is also an enthalpy recovery process, can be viewed as the collapse of highly disordered sites or 'defects'. The author has modeled this physical aging as a diffusion process in which the positive density fluctuation defects are annihilated by the corresponding negative ones. The diffusion constant depends on the concentration of defects, and each diffusion molecular jump induces hierarchically correlated molecular rearrangements which conform to a stretched exponential law. Good agreement was obtained between the theoretical and experimental volumes as well as enthalpy recovery results for poly(vinyl acetate) including the memory experiment and the variation of the effective relaxation time. (Edited author abstract) 30 refs.

Perez, J. (CNRS, Villeurbanne, Fr). *Polymer* v 29 n 3 Mar 1988 p 483-489.

## Blending

**083771 MORPHOLOGY OF POLY(ETHYLENE OXIDE)/POLY(VINYL ACETATE) BLENDS.** The morphology of poly(ethylene oxide)/poly(vinyl acetate) (PEO/PVAc) blends was examined using small angle X-ray scattering (SAXS) and optical microscopy. The morphological and structural parameters of the blends are dependent on both composition and crystallization conditions. Optical microscopy revealed that blend samples prepared by solution casting crystallized with volume-filling crystals up to a composition of 30/70 wt% PEO/PVAc; at higher PVAc content there was no evidence of crystallization in the temperature range studied. The morphological and structural properties of the PEO/PVAc blends were attributed to the presence of non-crystallizable material in both the interlamellar and interfibrillar regions. (Edited author abstract) 17 refs.

## Degradation

**083772 POLYMER PRECURSORS OF POLYACETYLENE. THERMAL DEGRADATION OF POLY(VINYL ESTERS). PART 1 - MOLECULAR WEIGHT DEPENDENCE OF THE AUTOCATALYTIC THERMAL DEGRADATION OF POLY(VINYL ACETATE) (PVAc).** This study is the first of a series on the pyrolyses of poly(vinyl esters) in which the kinetics of the isothermal degradation up to high conversions of five unfractionated heterotactic samples of poly(vinyl acetate) (PVAc) has been investigated by a static procedure in a nitrogen atmosphere over a wide temperature range. The experimental results can be explained by assuming the occurrence of a catalyzed deacetylation reaction which is first order with respect to  $\text{CH}_3 - \text{COOH}$  simultaneously with an uncatalyzed reaction. This kinetic model, based on the stripping mechanism, has been shown to be in very good agreement with the experimental data not only for low, but also for moderately high, degrees of conversion. Rate constants  $k_1$  and  $k_2$ , Arrhenius parameters  $E$  and  $A$  and  $\Delta S$  values have been determined for both the autocatalyzed and uncatalyzed elimination reactions. (Edited author abstract) 31 refs.

## Diffusion

**083773 MEASUREMENTS OF MASS DIFFUSION OF DYE MOLECULES IN POLYMER MATRIX BY THE FORCED RAYLEIGH SCATTERING TECHNIQUE.** A new type of photochromic dye molecules - bis-9-anthyl methyl ether is introduced as a potential

probe for diffusion studies of small molecules in polyvinyl acetate films using the forced Rayleigh scattering technique. It is shown that this technique is very effective for measuring diffusion coefficients as low as approx.  $10^{-14} \text{ cm}^2/\text{s}$ . The temperature-dependent diffusion coefficient of the free dye molecules in this polymer matrix is measured in the temperature range from 35°C to 90°C. The normal single exponential decay and the abnormal double exponential decay are also discussed. (Author abstract) 8 refs.

## Hydrolysis

**083774 METHODS OF INVESTIGATION. USE OF MICROCALORIMETRY FOR CALCULATION OF THE CONFORMATIONAL EFFECT IN POLYMER ANALOGOUS REACTIONS.** This paper proposes a quantitative approach to the estimation of the conformational effect in the hydrolysis of PVA using microcalorimetry. As a model hypothesis it is assumed that change in the conformation of the macromolecule due to change in the quality of the solvent or other factors may be described as an equivalent change in the conformation through pseudointramolecular crosslinking. Then to calculate the characteristics of such pseudo-crosslinked coils one may use in the known mathematical apparatus devised for intramolecular reactions. The method proposed has been used to calculate the kinetics of hydrolysis of PVA. 6 refs.

## Suspensions

**083775 OXYGEN QUENCHING STUDIES OF NONAQUEOUS DISPERSIONS OF POLY(VINYL ACETATE) LABELED WITH PHENANTHRENE GROUPS.** This paper describes experiments on nonaqueous dispersions of poly(vinyl acetate) (PVAc) particles sterically stabilized with poly(2-ethylhexyl methacrylate) (PEHMA). Particles were prepared with trace amounts of phenanthrene (Phe) groups covalently bound to either the PVAc core phase or the PEHMA stabilizer. Phe fluorescence was very similar in degassed samples of the two materials, but strong differences were noted in the presence of oxygen. Detailed oxygen fluorescence quenching studies provide information about particle morphology, about swelling of the stabilizer phase by the dispersion medium, particularly for PEHMA trapped inside the particle, and most importantly, about the PEHMA-PVAc interface. In the presence of the dispersion medium (cyclohexane), the interface is very diffuse: the presence of 7 wt% of PEHMA in the particle transforms nearly half the PVAc component into a phase swollen with cyclohexane and extremely permeable to oxygen. (Author abstract) 20 refs.

**083777 CONTACT ELECTRIFICATION OF CHEMICALLY MODIFIED SURFACES.** We have studied charge transfer from a variety of metals to solution-cast samples of polyvinyl-alcohol chemically treated to introduce superficial halogens (F, Cl, Br and I). Even though surface analysis shows that only a fraction of the hydroxyl groups are converted to halogen we find that the chemical treatments change the sign of the charge transfer from positive to negative; moreover, the charge transfer becomes much less dependent on metal work function as a result of the chemical treatment. Just such changes are expected if it is supposed that the Cl treatment (for example) converts the surface of the polymer from polyvinylalcohol to polyvinylchloride, and our experiments thus provide striking support for the opinion, expressed by many workers, that the contact electrification of polymers is intimately connected with their chemical composition. Chemical modification of a thin surface layer may provide a controlled means of adjusting the contact charging properties of a polymer with minimum disturbance of desirable bulk properties. (Author abstract) 18 refs.

**083778 EFFECT OF THE IONIC COMPOSITION OF THE SOLUTION ON THE POLYVINYL ALCOHOL ADSORPTION ON THE SURFACE OF  $\text{Al}_2\text{O}_3$ .** The adsorption of polyvinyl alcohol (PVA) from solutions of various ionic composition has been studied on alumina. In the presence of sodium dodecylsulphate (SDS) the complexes PVA-SDS are probably formed at the interface oxide-solution. The interaction between PVA and SDS at the interface leads to increase of PVA adsorption. However the presence of such complexes in the solution causes step-wise decrease of polyvinyl alcohol adsorption. The observed changes of surface charge density of alumina are in accord with the adsorption data. The estimated free energy of PVA adsorption on the surface of alumina is less than  $-9.7 \text{ kJ/mole}$ . (Author abstract) 20 refs.

## Aging

**083779 RHEOLOGICAL INVESTIGATION OF AQUEOUS SOLUTIONS OF POLY(VINYL ALCOHOL) DURING AGING - III. EFFECT OF THE THERMAL PREHISTORY OF THE POLYMER ON THE PROCESS OF AGING OF CONCENTRATED SOLUTIONS.** The paper deals with aging of concentrated poly(vinyl alcohol) solutions prepared from polymer samples which, prior to dissolution, were heated at various temperatures in an aqueous suspension or in the powder state. The effect of preheating is discussed on the basis of changes in viscosity and normal stress difference, measured during aging. (Author abstract) 6 refs.

Applications See EPOXY RESINS—Wear; PLASTICS FILMS—Manufacture.

## Biodegradation

**083780 BIODEGRADATION OF POLY(VINYL ALCOHOL) AND POLY(SODIUM ACRYLATE)-co-(VINYL ALCOHOL).** Biodegradation of poly(vinyl alcohol) (PVA) by microbes in the activated sludge of municipal sewage plants was studied. Two bacterial strains, *Pseudomonas* sp. M1 and *Pseudomonas putida* M2, were isolated as PVA-degrading strains. PVA was found to show excellent biodegradability. As a biodegrad-

able polyelectrolyte, poly[(sodium acrylate)-co-(vinyl alcohol)] [P(SA-VA)] which had the biodegradable vinyl alcohol units in poly(sodium acrylate) was prepared by the copolymerization of vinyl acetate with acrylic acid. It is biodegraded by the soil, and symbiotic bacterial strains of *Pseudomonas* sp. C1 and C2 were isolated and identified as P(SA-VA)-degrading strains. (Author abstract) 13 refs. In Japanese.

## Coloring

**083781 ON THE DISTRIBUTION OF DYE MOLECULES IN STRETCHED POLY(VINYL ALCOHOL).** The symmetry of the orientational distribution function of dye molecules in stretched PVA films is studied using polarized fluorescence. The different symmetries are monitored by a simple experimental technique in which angle-resolved fluorescence depolarization ratios are measured. A uniaxial distribution of rhodamine 6G molecules is obtained on stretching the film at temperatures above 60°C. In contrast, a biaxial distribution of trypanflavine molecules is found for stretch temperatures in the 50-115°C range. It is suggested that the hydrogen bonding between the PVA chains, and between the dye molecules and the PVA chains, influences the symmetry of the distribution upon stretching. (Author abstract) 28 refs.

## Elasticity

**083783 PROPERTIES OF SYNDIOTACTIC-RICH POLY(VINYL ALCOHOL) THIN FILMS IN WATER. VI. ELASTIC BEHAVIOR OF UNDRAWN/ANNEALED THIN FILMS BY REPEATED ELONGATION/CONTRACTION IN WATER.** The elastic behavior of undrawn/annealed swollen thin films of syndiotactic-rich poly(vinyl alcohol), derived from vinyl trifluoroacetate, was studied by repeated elongation/contraction in water. For the films annealed at temperatures below 175°C, the characteristic of deformation was divided into low-drawn and high-drawn regions. The elastic deformation was dominant over the plastic deformation in the low-drawn region and vice versa in the high-drawn region. The effect of heat treatment on the elastic behavior of the swollen films in water was almost independent of annealing temperatures below 125°C. The elastic deformation in water at 70°C was especially remarkable in the low-drawn region for the films annealed at temperatures below 125°C and at 80°C for the films annealed at 150°C. For the films annealed at 200°C, considerable plastic deformation occurred in addition to elastic deformation from the initial drawing. (Edited author abstract) 8 refs.

## Film

**083784 EXTRACTION OF ABSORPTION SPECTRA OF SOME POLYENES PRODUCED IN POLY(VINYL ALCOHOL) FILM UTILIZING PHOTODEGRADATIONS BY MONOCHROMATIC LIGHT.** Individual absorption spectra of  $-(CH=CH)_n-$  ( $n=2-5$ ) produced in heated poly(vinyl alcohol) (PVA) films can be extracted separately by selective photodegradation. Difference spectra between the two spectra obtained at various different irradiation times did not show the spectra of individual polyenes owing to overlapping of the spectra due to degraded and produced polyenes. By proper combination of irradiations, however, the other spectra could be eliminated, and each spectrum of  $n=2-5$  could be extracted. For  $n=4$  and 5, the second bands were revealed. (Author abstract) 10 refs.

**083785 STRUCTURE OF POLY(VINYL ALCOHOL)-IODINE COMPLEX IN WATER SWOLLEN FILM.** The structure of a poly(vinyl alcohol) (PVA)-iodine complex was investigated by a resonance Raman spectroscopy, wide angle X-ray diffraction, small angle X-ray scattering, NMR and IR spectroscopies. The results show that some changes in the state of hydrogen bondings are induced by complexation. The weight of the PVA film increased rapidly by iodine sorption at the first stage and then decreased. The changes of the long period and volume took place rapidly, being followed by much slower increase in Young's modulus. The ratio of the decrease in volume was much larger than that of the long period. It was assumed that the fast contraction in iodine-soaking was mainly due to the release of water out of membranes induced by iodine-sorption but not due to the complexation. (Edited author abstract) 19 refs.

## Measurements

**083786 FORCES BETWEEN ADSORBED PVA LAYERS.** The forces between adsorbed layers of poly(vinyl alcohol) have been measured by a direct force balance technique. Not only have the equilibrium forces been measured, but also the dynamic forces have been assessed as the surfaces were rapidly moved towards each other. It was found that the dynamic forces were larger by a substantial factor than those measured at equilibrium, and this has important implications for the stability of colloidal dispersions stabilised by adsorbed polymer layers, and possibly also for electrostatically stabilised colloids. (Author abstract) 4 refs.

Lubetkin, Steven (Univ of Bristol, Bristol, Engl). *Colloids Surf* v 31 May 1988, Polym in Colloid Syst: Adsorpt, Stab and Flow, Proc of an Int Conf, Veldhoven, Neth, Sep 7-9 1987 p 203-209.

## Modification

**083787 NEW MODIFICATIONS OF POLY(VINYL ALCOHOLS) AND THEIR APPLICATIONS.** Poly(vinyl alcohol) (PV-OH), prepared from poly(vinyl acetate), is used widely in many industries. Various grades have been produced, with different degree of polymerization and degree of hydrolysis. Recently, novel modified (PV-OH)s with anion, cation, silanol or hydrophobic groups have been studied and developed. They have new properties in addition to those of ordinary PV-OH and have new applications. The methods of modification and the characteristics and some applications of the modified polymers are described. (Author abstract) 28 refs.

**Molecular Weight** See GRAFT COPOLYMERS—Synthesis.

## Permeability

**083788 EFFECT OF RETORTING ON THE BARRIER PROPERTIES OF EVOH.** The effect of retort processing and storage conditions on the oxygen permeability of ethylene vinyl alcohol copolymer (EVOH) in multilayer packaging was studied. Immediately after retort processing, the oxygen permeability of EVOH increases due to plasticization by moisture. An irreversible effect of retorting on permeability is also seen though. This increase in permeability is attributed to the creation of excess free volume. Based on these experimental results, mathematical models were developed to predict EVOH oxygen permeability given the retort history and storage conditions. It is also found that incorporating desiccant in the multilayer structure overcomes the moisture effect and greatly reduces the retort path dependence. (Author abstract) 6 refs.

## Physical Properties

**083789 PROPERTIES OF SYNDIOTACTIC-RICH POLY(VINYL ALCOHOL) THIN FILM IN WATER. V. EFFECT OF INITIAL TEMPERATURE OF HEATING ON ELONGATION.** The effect of the initial temperature of heating on the elongation of syndiotactic-rich poly(vinyl alcohol) thin films was investigated in water under a load. The elongation ratios  $E_t$  after 4 h at fixed temperatures increased roughly with an increase in the initial temperature  $T_i$  and a decrease in the annealing temperature.  $E_t$  after 4 h was the smallest at  $T_i = 45^\circ\text{C}$  for the films annealed at temperatures below  $100^\circ\text{C}$ .  $E_t$  was 6.8 at  $T_i = 60^\circ\text{C}$  for the unannealed film and 1.12 at  $T_i = 70^\circ\text{C}$  for the film annealed at  $200^\circ\text{C}$ . The elongation at break decreased and the temperature at break increased with an increase in annealing temperature, but those at the annealing temperature of  $100^\circ\text{C}$  were the smallest. The films annealed at  $200^\circ\text{C}$  did not break even at  $98^\circ\text{C}$  (boiling temperature) in water and the elongation ratio was 1.42-1.97 in the initial temperature range of  $10-70^\circ\text{C}$ . From these results, the relation between the elongation in water and the state of polymer chains in film was discussed. (Author abstract) 10 refs.

Yamaura, Kazuo (Shinshu Univ, Ueda, Jpn); Masuzawa, Tatsuaki; Tanigami, Tetsuya; Matsuzawa, Shuji. *J Appl Polym Sci* v 35 n 3 Feb 20 1988 p 593-600.

**083790 PROPERTIES OF BLENDS OF SYNDIOTACTIC-RICH AND ATACTIC POLY(VINYL ALCOHOLS).** The crystallinity, solubility, degree of swelling, and hygroscopicity of the blends of syndiotactic-rich (st-PVA) and atactic poly(vinyl alcohols) (at-PVA) were studied. The crystallinity of the blends increased with increasing annealing temperature and that of the blends annealed at  $200^\circ\text{C}$  was larger than that of at-PVA. In the  $200^\circ\text{C}$  annealed blends containing st-PVA about 50%, the insoluble fraction in boiling water was larger than the fraction of st-PVA in each blend. The soluble fraction for the blend containing 75% st-PVA was 1.7%. The moisture regain of the blends was less than that of at-PVA. (Author abstract) 7 refs.

## Radiation Effects

**083791 SPECTROSCOPIC STUDIES OF PHOTO-CONVERSION IN POLYVINYL ALCOHOL UNDER THE INFLUENCE OF INFRARED AND ULTRAVIOLET RADIATION.** In the present work a comparative spectroscopic study of structural changes in polyvinyl alcohol (PVA) under the influence of IR- and UV-radiation has been carried out. The authors used PVA produced by alkaline saponification, which was first purified by double reprecipitation in acetone. Films were decanted for use in the study from 10% water solution of PVA. The thickness of the samples stood at 0.03-0.05 mm. A mean pressure mercury lamp of type PRK served as the source of radiation. It was discovered that under the action of these types of radiation there occurred a decrease in the optical density and a small  $200\text{-cm}^{-1}$  displacement in wavenumber of the electron absorption band maximum in the region of  $35,400\text{ cm}^{-1}$  (283 nm) in the UV-spectrum of PVA. 23 refs.

Rheology See GELS—Rheology.

## Solutions

**083792 CRYSTAL GROWTH IN SYNDIOTACTIC POLY(VINYL ALCOHOL) HYDROGELS.** Aqueous solutions of syndiotacticity-rich poly(vinyl alcohol) (s-PVA) form gels easily. The optimum condition of growth of the calcium tartrate crystal formed by diffusing calcium chloride into hydrogels containing tartaric acid was studied with use of s-PVA of a syndiotacticity of 56% and a degree of polymerization of 1460. The crystal grew in the gel of the concentrations of 2% s-PVA and of 0.5 N tartaric acid at pH=4. The relation between the formation of Liesegang rings and shear modulus of a gel was studied by diffusing silver nitrate into gel containing potassium chromate. The distance between rings decreased with increasing shear modulus of a gel in the range from 670 to 7500 dyne/cm<sup>2</sup>. The Liesegang rings were not formed for the shear modulus gel for 280 and 16200 dyne/cm<sup>2</sup>. (Author abstract) 18 refs.

**083793 GELS OF SYNDIOTACTICITY-RICH POLY(VINYL ALCOHOL) - WATER/DIMETHYL SULFOXIDE OR - WATER/ETHYLENE GLYCOL SOLUTIONS.** Gels of syndiotacticity-rich poly(vinyl alcohol) in mixed solvents of water/dimethyl sulfoxide (DMSO) or water/ethylene glycol were made by chilling at the temperatures of 0-70°C from those solutions with the polymer concentrations below 10 g/dL. The melting points of the gels were measured warming the gel from the gelling temperature at a constant heating rate. The apparent enthalpy of fusion of a junction of gel, was estimated from the relation between the apparent melting temperature and the polymer concentration. (Edited author abstract) 14 refs.

**083794 SPECTROPHOTOMETRIC DETERMINATION OF POLY(VINYL ALCOHOL) IN CADMIUM HYDROXIDE PASTES.** A colorimetric method has been developed to spectrophotometrically determine the poly(vinyl alcohol) (PVA) content of aqueous Cd(OH)<sub>2</sub> pastes. The method, which is based upon the formation of a blue PVA-iodine-boric acid complex, can quantitatively determine PVA in aqueous solution concentrations of 2-40 mg/L corresponding to PVA levels within the paste as low as 0.02%. Solution absorbance of the complex, however, depends upon the concentration of Cd<sup>2+</sup> in solution necessitating cognizance of this level for routine quantitative analysis. (Author abstract) 11 refs.

**083795 INVESTIGATION OF AGING AQUEOUS POLY(VINYL ALCOHOL) SOLUTIONS BY THE LIGHT SCATTERING METHOD.** Aqueous poly(vinyl alcohol) solutions of various concentrations were investigated. The aged solutions were diluted and then analyzed by the light scattering method, size exclusion chromatography, and viscometry. It was found that a relatively small quantity of supermolecular formations arise during aging; they are dispersed in the molecular solution of the predominant part of the polymeric material present. The amount of these aggregated structures and their formation rate increase with concentration of the aging solution. (Author abstract) 23 refs.

**083796 <sup>11</sup>B N.M.R. STUDY ON THE REACTION OF POLY(VINYL ALCOHOL) WITH BORIC ACID.** The crosslinking mechanism of an aqueous alkaline solution of poly(vinyl alcohol) (PVA) in the presence of boric acid was investigated by means of <sup>11</sup>B nuclear magnetic resonance (nmr). 2-Propanol and 2,4-pentandiol were chosen as monomeric and dimeric model samples of PVA, respectively. In the case of 2-propanol, only one strong signal was observed, which was the same as in the case without alcohol. By pentandiol and PVA. It is concluded that monohydroxyl alcohol does not react with boric acid, whereas diand polyhydroxyl alcohols having the structure of 1,3-diol do. (Edited author abstract) 16 refs.

Shibayama, Mitsuhiro (Kyoto Inst of Technology, Tokyo, Jpn); Sato, Masahiro; Kimura, Yoshiharu; Fujiwara, Hiroshi; Nomura, Shunji. *Polymer* v 29 n 2 Feb 1988 p 336-340.

**083797 THERMOREVERSIBLE GELATION OF SOLUTIONS OF POLY(VINYL ALCOHOL).** The thermoreversible gelation of solutions of poly(vinyl alcohol) in ethylene glycol was investigated by calorimetric and optical observations, X-ray scattering techniques and rheological measurements. The gelatin that occurs on cooling to room temperature results from a liquid-liquid demixing, followed by a crystallization of the polymer in the concentrated domains. As a consequence of the two-phase morphology, practically no molecular orientation is observed when the gels are stretched. Gelatin at high temperature, above the region of liquid-liquid demixing, originates from a slow crystallization from solution. (Edited author abstract) 15 Refs.

Stoks, W. (Univ Leuven, Leuven, Belg); Berghmans, H.; Moldenaers, P.; Mewis, J. *Br Polym J* v 20 n 4 1988 p 361-369.

**083798 INHIBITION PERIOD OF VINYL ACETATE MONOMER IN SUSPENSION, EMULSION AND BULK POLYMERIZATION AT 730 mm Hg AND 760 mm Hg.** A trend in the inhibition period of vinyl acetate monomer (VAM), using benzoyl peroxide (Bz<sub>2</sub>O<sub>2</sub>), azobisisobutyronitrile (AIBN) and potassium peroxy disulphate (K<sub>2</sub>S<sub>2</sub>O<sub>8</sub>), during suspension, emulsion and bulk polymerizations, with change in pressure from 730 mm Hg to 760 mm Hg is reported. From the inhibition period determinations at 730 and 760 mm Hg in suspension and emulsion polymerizations of VAM it is concluded that not only with Bz<sub>2</sub>O<sub>2</sub> (reported earlier) but with other initiators such as AIBN and K<sub>2</sub>S<sub>2</sub>O<sub>8</sub> the inhibition period of VAM increases with decrease in pressure. In bulk polymerization, with both Bz<sub>2</sub>O<sub>2</sub> and AIBN initiators, due to increase in concentration of dissolved oxygen present, the inhibition period increases with increase in pressure. (Edited author abstract) 12 Refs.

## Spectroscopic Analysis

**083799 POLARIZED SPECTRA OF A SERIES OF STILBAZOLIUM MERCOCYANINES IN POLYVINYL ALCOHOL FILMS.** Polarized absorption, fluorescence and photoacoustic spectra of a series of stilbazolium merocyanines in stretched and unstretched polyvinylalcohol films were measured. Protonated dyes and free based are present in PVA films. The degree of orientation of the dye molecules depends on the substituents present in the molecule. The bulky t-butyl causes a decrease in the degree of orientation and prevents the formation of ground state complexes. In the excited state, the steric hindrance is less important and exciplexes are formed. Only ground state complexes and exciplexes fluoresce. The excitation of monomers is followed by effective thermal deactivation. Ground state complexes and exciplexes have different geometries. Axial deformation of PVA films favours excimer formation, but causes a partial dissociation of the ground state complexes. (Author abstract) 14 refs.

## Spectrum Analysis

**083800 CONCENTRATION DEPENDENCE OF SPECTRAL POLARIZATION CHARACTERISTICS OF IMPURITY FLUORESCENCE IN POLYMERS.** In the course of studies on the polarized luminescence of stretched polyvinyl alcohol (PVA) films activated by proflavin and oxadiazole derivatives, we have discovered some spectral and orientational inhomogeneity: the fluorescence anisotropy R<sub>0</sub>, which is due to molecular orientation, decreases abruptly in the long-wavelength part of the fluorescence spectrum. The elucidation of this inhomogeneity constitutes the aim of this work. 13 refs.

## Synthesis

**083801 STUDIES ON POLYVINYL ALCOHOL CARRIERS: III. ACTIVE AMIDES AND ESTERS DERIVED FROM POLYVINYL ALCOHOL AND THEIR APPLICATION IN AFFINITY CHROMATOGRAPHY.** Polyvinyl alcohol carriers bearing active amide and active ester groups were prepared by acetalization of granular macro-reticular water-insoluble PVA with glyoxylic acid or p-formylbenzoic acid and further activation reaction with benzotriazole or N-hydroxysuccinimide using DCCI as condensation agent. The active amides or active esters obtained were easy to react with amines such as n-butylamine or proteins under mild condition. Ovomuroid, an inhibitor of trypsin was immobilized on the above-obtained reactive PVA carrier to give effective affinity adsorbent for the separation or purification of trypsin. (Author abstract) 7 refs.

Li, Fumian (Peking Univ, Beijing, China); Wang, Lin; Feng, Xinde. *Chin J Polym Sci (Engl Ed)* v 4 n 4 Feb 1987 p 297-302.

**083802 PREPARATION OF HIGH MOLECULAR WEIGHT POLY(VINYL ALCOHOL).** Emulsion polymerizations of VAc were carried out at low temperature to obtain high molecular weight polymer. In the course of study it was found that some of them gave PVA of larger P<sub>n</sub> (average degree of polymerization) than 1×10<sup>4</sup> after hydrolysis of PVAc obtained. This method is simple and is described in this paper. 5 refs.

**Thin Films** See Also PLASTICS FILMS—Spectroscopic Analysis.

**083804 ELECTRICAL PROPERTY OF ULTRA THIN FILM OF POLYVINYLALCOHOL.** Electrical properties of ultra thin PVA films (several hundreds Å-several µm in thickness) formed by sphere bulb blowing, solution surface scooping and casting techniques are studied. The electrical conductivity of relatively thick films (> several thousands Å) is very high and is enhanced by the exposure either to high humidity of air or NH<sub>3</sub>, which can be explained in terms of the role of ionic transport. The use of PVA film as NH<sub>3</sub> sensor is also proposed. In ultra thin PVA films less than 1500 Å, two conducting states, namely, a high-conducting and a low-conducting one, are observed. The nonlinear current-voltage characteristics in the low conducting state and the switching between these two states are also confirmed. These properties are discussed in terms of electronic conduction processes. (Edited author abstract) 3 refs.

**POLYVINYL CHLORIDE** See Also BIOMEDICAL EQUIPMENT—Evaluation; ELECTRODES—Materials; PIPE, PLASTIC—Drainage; PLASTICS—Blending; PLASTICS, REINFORCED—Fracture; POLYMERIZATION; POLYURETHANES—Blending; VINYL RESINS—Crystallization.

**083805 KINETICS OF ABSORPTION OF N-ALKYL PHTHALATE PLASTICIZERS INTO PVC RESIN PARTICLES.** The kinetics of plasticizer absorption by suspension polymerized polyvinylchloride (PVC) have been investigated. The volume swelling ratios of individual PVC particles, immersed in excess plasticizer, were recorded over a period of time using an optical microscope equipped with a high-speed camera. Absorption of di-n-decylphthalate was studied in the range 70 < T < 100°C. The study shows that the uptake of plasticizer proceeds in three steps. Temperature dependency of rate of absorption in the slow initial step was fitted to an Arrhenius expression, and an activation energy for plasticizer uptake was calculated. (Edited author abstract) 5 refs.

**083806 BADANIA STOPNIA ZZELOWANIA PLASTYFIKATOW POLICHLORKU WINYLU I KOPOLIMEROW CHLORKU WINYLU Z OCETANEM WINYLU.** [Evaluation of Degree of Gelation of Plasticized PVC and Vinyl Chloride-vinyl Acetate Copolymer]. The influence of rolling temperature on the melt flow index (MFI) of plasticized polyvinyl chloride and VC-VAc copolymer has been studied. On this basis, the degree of gelation has been determined. The model of relation between the structural changes occurring in plasticized compositions during gelation and MFI has been presented. A direct correlation between the degree of gelation and the tensile strength has been established. (Edited author abstract) In Polish. 7 refs.

Zajchowski, Stanislaw; Piszczek, Kazimierz; Skraga, Jan. *Przem Chem* v 66 n 8 Aug 1987 p 383-385.

**083807 COMPATIBILITY OF PVC WITH POLYURETHANES OF DIFFERENT SOFT SEGMENTS.** Blends of PVC and polyurethanes with four different soft segments of molecular weight 1000 were prepared and studied by dynamic mechanical and DSC techniques. It was found that the compatibility of PVC with segmented polyurethanes was related to the mixing of PVC molecules and the soft segments of the polyurethanes. Polyester based polyurethanes are more compatible with PVC than polyether based polyurethanes. Solution cast blends of PVC with PCL-polyurethane (1/2/1) exhibit single and narrow glass transition, while the blends with PPO-polyurethane (1/2/1) are completely incompatible. The compatibility was found to decrease with increasing hard segment contents for all the polyurethanes used. The methods of blend preparation may change the compatibility of PVC/PU blends through their influence on the mixing or demixing of the hard and soft segments. (Author abstract) 25 refs.

**083808 PVC: THE ISSUES.** Proceedings incorporates 22 papers that are arranged in four sessions dealing with: regulatory/liability issues; flammability and smoke; disposal and recycling; and leaching, diffusion, permeation and toxicity. Topics covered include: metal-oxide colors used for coloring vinyls, ceramic materials, lead stabilizers, cadmium pigments, environmental regulations, vinyl chloride monomers, water pollution, diffusion science, marketing of products made of plastic rubbish, municipal disposal of solid wastes, landfills, incineration, PVC smoke, combustibility of vinyl sidings, electrical codes requirements for telecommunication and electric cables, fire resistant materials, measurements of smoke parameters, NBS standards and measuring equipment, calorimeters, product liability, legal aspects, health hazards, combustion toxicity controversy, packaging and bottling of alcoholic beverages, and food products. Technical and professional papers from this conference are indexed and abstracted with the conference code no. 11656 in the Ei Engineering Meetings (TM) database produced by Engineering Information, Inc.

Anon (Soc of Plastics Engineers, Vinyl Div, Palisades Section, USA). *Tech Pap Reg Tech Conf Soc Plast Eng* 1987, PVC: The Issues, Atlantic City, NJ, USA, Sep 16-17 1987. Publ by Soc of Plastics Engineers, USA 224p.

**083809 PROBY MODYFIKACJI OBUWNI CZEGO POLICHLORKU WINYLU PROSZKIEM GUMOWYM.** [Preliminary Experiments on the Modification of Footwear-Grade PVC with Rubber Powder]. With the aid of the method of statistical planning of experiments, the effect of the content of waste-grade silica (up to 10% by weight) and rubber powder (up to 20% by weight), as well as the degree of fineness of the powder, on the coefficient of friction of footwear-composition is evaluated on the basis of PVC of Polwiplast SBD grade. The coefficient of friction has been measured in the temperature range of 273-323 K (0-50°C) and for loads in the range of 11,300-55,000 Pa. It has been found that an addition of 5% silica (grain diameter of 0.2 µm) and 10% rubber powder (grain diameter 0.2 or 0.5 µm) has an advantageous effect on the frictional properties of the composition. (Edited author abstract) 3 refs. In Polish.

**083810 COMPUTERIZED PVC FORMULATING FOR OPTIMIZED COST/PERFORMANCE.** A broad data base is required to capitalize on the many cost effective options posed to the PVC formulator. The Marketing Technical Service function of Exxon Chemical Co. utilizes COPPCO, Computerized Profit/Performance

Consulting, to evaluate the options. The coherent data base contains 34 different plasticizers ranging from 25 to 90 phr, and can accommodate filler effects over a range of zero to 100 phr. The functions performed by COPPCO are outlined. COPPCO utilizes SAS (Statistical Analysis System) and Telegraph graphics, combined with sophisticated mainframe programs developed specifically to provide the desired output. (Edited author abstract). 6 refs.

## Adhesion

**083811 ADHESION MECHANISM OF POLYVINYL CHLORIDE TO SILANE PRIMED METAL SURFACES.** The interface of partially hydrolyzed organosilane primer Dow Corning Z-6020 [N-(2-aminoethyl-3-aminopropyl trimethoxy silane), which is referred to in this paper as simply AEAPS, and polyvinyl chloride (plastisol) was examined by XPS (X-ray photoelectron spectroscopy) depth profile analysis. These studies and the adhesion strength measurements under dry and wet conditions showed that the net bond strength and its resistance to moisture are determined by two factors: the extent of crosslinking of the primer and the interdiffusion of the two phases. Best adhesion is achieved as a result of the optimal balance between the above two conflicting tendencies, i.e. when the primer crosslinks after it has diffused into the polymer. (Edited author abstract) 30 refs.

## Aging

**083812 GLASS TRANSITION AND PHYSICAL AGEING IN PLASTICIZED POLY(VINYL CHLORIDE).** Several samples of poly(vinyl chloride), both unplasticized and plasticized with dioctyl phthalate, have been examined by differential scanning calorimetry. It was observed that, while the glass transition temperature T<sub>g</sub> decreased as expected with increasing plasticizer content, a small portion of the sample appeared to be resistant to the plasticizer. This was manifest in the appearance of a second T<sub>g</sub> corresponding to the unplasticized sample which remained unaffected by the addition of plasticizer. The aging behavior of the samples was also examined using enthalpy relaxation measurements and it was observed that the presence of plasticizer accelerates the aging process, probably due to the fact that there is greater mobility of the chains in the plasticized samples. (Author abstract) 24 refs.

**083813 NEW GENERATION, LOW TASTE AND ODOR, HIGH CLARITY, LOW BLUSH VINYL COMPOUNDS.** A new compound for vinyl bottle applications has outstanding taste and odor properties, good thermal stability and color, excellent clarity, gloss, and blush resistance, solving many of the traditional problems associated with these applications. It is shown that blush (haze developed on exposure to alcohol/water)

cannot be accelerated, but should be measured by aging at the maximum temperature at which the product is likely to be exposed. (Author abstract) 15 refs.

**083814 PIGMENTED AND HIGHLY TRANSPARENT IMPACT RESISTANT PVC FOR OUTDOOR APPLICATION.** A comparison of results gained over the past years with open air weathering trials of pigmented, impact resistant PVC and those of artificial ageing show that the accelerated weathering units give as good an indication to the suitability of this material for outdoor application. The suitability of a transparent, impact resistant PVC formulation for external use is being investigated at present. (Author abstract) 5 refs. In German and English.

Hepp, D. *Kunstst Ger Plast* v 77 n 11 Nov 1987 p 28-30, 1177-1179.

**083815 SHRINKAGE FORCES AND TEMPERATURE-DEPENDENT CHANGE IN LENGTH IN PLASTICIZED PVC ROOFING SHEETS.** The cause of the shrinkage forces is a plasticizer loss influenced by the sheet formulation and the method of laying. No pronounced isotropy of the forces was observed in films. A relationship with the constitution of the plasticizer could not be established. Measurement of the free elongation of the specimen strain shows that both reversible and irreversible changes in length can occur. Coated fabrics are subject to lower fluctuations than films. With coated nonwovens, the type and structure of the nonwoven are of major importance. (Author abstract) 8 refs. In German and English.

**083816 EXTRUDATE MORPHOLOGY OF BLENDS OF PLASTICIZED POLY(VINYL CHLORIDE) AND THERMOPLASTIC COPOLYESTER ELASTOMER.** Properties of polymer blends are highly dependent on their morphology. During the last few years, several studies have been reported on the morphology of various polymer blends. The phenomena of segregation, stratification, and phase inversion of heterogeneous polymer blends have been reported by various researchers. Blends of copolyester thermoplastic elastomer (hytel 40 D) and plasticized PVC combine the physical properties of hytel and the excellent processing characteristics of PVC. These blends are popularly used in a variety of applications. Rheology, relationship between morphology and mechanical properties, failure behavior, compatibility, and radiation resistance of these blends have been studied. No studies have been undertaken with respect to the extrudate morphology. In this paper we report the results of our studies on the extrudate morphology of hytel-PVC blends with special reference to the effect of blend ratios and extrusion shear rates. 23 refs.

**083817 ABS AND CPE MODIFIERS IN RIGID PVC.** A comparison of acrylonitrile butadiene styrene (ABS) and chlorinated polyethylene (CPE) as PVC modifiers showed ABS to improve processability at low concentrations. CPE is more effective at high levels. Almost all the modifiers improved impact strength dramatically at 10 parts per hundred of resin. CPE containing 36 percent chlorine was the most effective, but reduced PVC modulus and heat-deflection temperature more than ABS. (Author abstract) 16 refs.

**083818 STUDIES ON MORPHOLOGY, MECHANICAL PROPERTIES AND FAILURE MODE OF BLENDS OF PLASTICIZED POLY(VINYL CHLORIDE) AND THERMOPLASTIC COPOLYESTER ELASTOMER.** Morphology and mechanical properties of blends of plasticized poly(vinyl chloride) (PVC) and thermoplastic copolyester elastomer (Hytel 40D) have been studied with special reference to the effect of blend ratios. Morphology of the blends indicates that the Hytel phase is dispersed as domains in the continuous PVC phase up to 75 percent of its concentration. Dynamic mechanical analysis of the blends shows marginal level of compatibility between the two phases. The mechanical properties depend on the proportion of thermoplastic rubber in the blend. Attempts have been made to correlate the blend morphology with properties. Failure surfaces were examined by scanning electron microscope and it was found that the fractographs depend on the type of failure (tensile or tear) and on the blend composition. (Author abstract) 48 refs.

**083819 COMPATIBILITY OF BLENDS OF POLY(VINYL CHLORIDE) WITH POLY(METHYL METHACRYLATE).** IR spectral shifts of carbonyl vibrational absorption for ethyl acetate, which acts analogically as the structural unit of poly(methyl methacrylate), in cyclohexane, chloroform, chlorinated paraffins, poly(vinyl chloride) and chlorinated poly(vinyl chloride) were measured. The results suggest that there are specific interactions between the carbonyl groups and the chlorinated hydrocarbons which could be responsible for the apparent compatibility of poly(vinyl chloride)-poly(methyl methacrylate) and chlorinated poly(vinyl chloride)-poly(methyl methacrylate) blends. Additionally, the effects of the preparation mode of blend films on phase separation and observed compatibility are discussed. (Author abstract) 12 Refs.

Wang, Qingguo (Nanjing Univ, Nanjing, China); Cheng, Rongshi. *Chin J Polym Sci (Engl Ed)* v 6 n 2 1988 p 186-191.

**083820 BLENDING NBR POWER WITH PVC.** The deficiencies of the conventional plasticizing systems used in polyvinyl chloride (PVC) can be improved or eliminated by the addition of nitrile rubber to the PVC compound. The introduction of a finely divided powder form of the material has brought the potential for PVC/NBR alloys to smaller compounders with conventional dry-blend mixing. Adding the nitrile powder to a PVC compound significantly reduces, and in some applications completely eliminates, the loss of plasticizer due to volatilization, migration, or extraction. Elongation retention after heat aging for 168 hours at 235°F and in extractive-fluid aging with hexane, cooking oil, and Type II fuel is 50 percent better than the all-PVC compound.

## Chemical Reactions

**083821 STEREOSELECTIVE SUBSTITUTION ON PVC USING PHASE TRANSFER CATALYSTS.** The nucleophilic substitution with sodium benzenethiolate in aqueous suspension in the presence of a phase-transfer catalyst has been studied for two samples of PVC of different tacticities. The kinetics show two well-defined periods: one period is very fast and involves low conversions that are greater as the isotactic content of PVC increases, while another steady period is slow and its slope seems to depend on physical features, e.g., molecular weight and crystallinity, which would affect the accessibility of nucleophile. The evolution of unreacted syndio, iso, and heteroactic triad contents with degree of substitution has been followed by <sup>13</sup>C-NMR spectroscopy. The influence of degree of substitution on both the thermal degradation rate and the evolution of UV-Visible spectra of equally degraded samples has been also studied. (Edited

**083823 CONVERSION DISTRIBUTION IN DIFFUSION-GOVERNED CHLORINATION OF POLY(VINYL CHLORIDE).** Conversion distribution in particles of chlorinated poly(vinyl chloride) (CPVC) is conceptually described based on balance equations involving mass transfer and chemical reaction. In the physical sorption of chlorine in poly(vinyl chloride) (PVC) as measured by the constant volume cell method, equilibrium concentration and diffusion rate obeyed Henry's law and Fick's law. The rate process of photo chlorination of PVC, which was investigated by the gravimetric method, could be well predicted by theoretical calculation of chlorine diffusion in PVC accompanying the infinitely fast chemical reaction. ## Chromatographic Analysis

**083824 STUDY ON THE GPC CONCENTRATION EFFECT OF PVC.** The GPC concentration effect has been investigated in THF at 25°C for polydispersed PVC samples. The experimental results show that the GPC elution volume is a linear function of concentration. A new simplified model theory proposed by Song for concentration dependence of GPC elution volumes agrees well with the experiments. The second virial coefficients of PVC determined from GPC concentration effect by the calibration of the polydispersed PVC samples are  $0.84 \times 10^{-3}$ ,  $1.0 \times 10^{-3}$  and  $1.32 \times 10^{-3}$ , respectively. (Edited author abstract) 9 Refs. In Chinese.

**Combustion** See Also HYDROGEN INORGANIC COMPOUNDS—Degradation.

**083825 QUICK METHOD FOR DETERMINING THE ACID GAS EVOLUTION FROM PVC FORMULATIONS.** A method has been developed for the determination of the amount of acid gas produced during the thermal decomposition of PVC formulations. A method was required to support a program to reduce acid gas generation by retention of hydrogen chloride in the char phase. The traditional method (a modified Schoeniger) produces inaccurate and irreproducible results due to uncontrolled combustion. Other methods often take an excessive amount of time to run and may need expensive and unusual equipment. The test described here is accurate, fast, reliable, reproducible, and requires equipment which is readily available in a typical chemical laboratory. The method is based on the modified Schoeniger test, but the sample is thermally decomposed by the action of a small coil of electrical resistance wire. The sample is held in a porcelain boat inside the heating coil. (Edited author abstract) 8 refs.

**083826 COMBUSTION TOXICOLOGY OF POLYVINYLCHLORIDE REVISITED.** The combustion toxicology of polyvinylchloride (PVC) has been studied extensively against a background of increasing understanding of the relevance of the toxicity of combustion products in fires. Most materials have a similar toxic potency and demonstrate asphyxia and irritancy when thermally decomposed. Hydrogen chloride is a major toxicant produced by PVC, which accounts for the irritancy shown by PVC combustion products. Carbon monoxide is also produced which becomes the most significant toxicant if the hydrogen chloride levels are reduced, which can occur rapidly in fires. The toxic potency lies within the range of 300-3000 mg/l. mins, which is similar to the majority of polymeric materials whether natural or synthetic. (Edited author abstract) 40 refs.

## Crack Propagation

**083829 FATIGUE CRACK PROPAGATION IN UNPLASTICIZED POLY(VINYL CHLORIDE): 1. EFFECT OF MEAN STRESS.** The effect of mean stress on fatigue crack growth in an unplasticized poly(vinyl chloride) (uPVC) pipe material was investigated using single-edge-notched (SEN) specimens and the results analyzed in terms of fracture mechanics. Three series of experiments were conducted. In the first the fatigue crack growth rates  $da/dN$  were collected as a function of the applied stress intensity factor range  $\Delta K (=K_{max} - K_{min})$  by keeping the stress ratio  $R (=K_{min}/K_{max})$  constant. In the second series of experiments  $da/dN$  were obtained as a function of  $\Delta K$  when the mean stress intensity factor  $K_m$  was constant; and in the third series  $\Delta K$  was maintained constant,  $da/dN$  were obtained with increasing  $K_m$ . All experimental results were obtained and processed using computerized data acquisition systems. (Edited author abstract) 34 refs.

Kim, Ho-Sung (Univ of Sydney, Sydney, Aust); Truss, Rowan W.; Mai, Yiu-Wing; Cotterell, Brian. *Polymer* v 29 n 2 Feb 1988 p 268-276.

**083830 FATIGUE CRACK PROPAGATION IN UNPLASTICIZED POLY(VINYL CHLORIDE) (uPVC): 2. NEAR-THRESHOLD FATIGUE CRACK GROWTH.** A new computer-aided test method was developed to measure near-threshold fatigue crack growth rates for a 150 mm class 12 uPVC pipe. A computer program was written to drive the fatigue testing machine and an optical microscope of 0.01 mm resolution was used to determine crack growth in the single-edge-notched

specimen. The efficiency and advantages of this new technique are discussed and compared to the current ASTM proposed method. For crack growth rates of the order of  $10^{-9}$  m cycle<sup>-1</sup> the present computerized method are approximately seven times more efficient and therefore greatly minimized the testing times required to collect near-threshold fatigue data. Using this method the effects of stress ratio and level of processing on the near-threshold fatigue crack growth were investigated. (Edited author abstract) 26 refs.

## Crosslinking

**083831 TERMOOXIDACNI STARNUTI MEK-CENYCH SVETLEM SITOVANYCH PVC SMESI [Thermo-Oxidative Aging of Plasticized PVC Compounds Crosslinked by Light].** Changes in tensile properties of light-crosslinked plasticized PVC compounds during thermo-oxidative aging at 100° and 130°C have been examined. The changes in tensile properties are not significant enough to prevent the light-crosslinked plasticized PVC to be utilized in general-purpose products. The above compounds containing the stabilizing systems tested are not very suitable for a high-temperature usage. (Author abstract) In Czech. 9 refs.

Malac, Jiri (Vyzkumny Ustav Gumarenske a Plastikarske Technologie, Gottwaldov, Czech); Rektorikova, Libuse; Sumberova, Jirina. *Plasty Kauc* v 24 n 10 Oct 1987 p 306-311.

**083832 CROSSLINKING OF POLY(VINYL CHLORIDE).** Crosslinking of polyvinyl chloride (PVC) using a diamine such as ethylenediamine (EDA) as the crosslinking agent was studied. Studies were mostly made with unfilled compounds but the effects of fillers such as  $CaCO_3$  and  $Ca(OH)_2$  were also examined. The effects of variation of EDA content and the time of crosslinking at 170°C on the gel content (%), thermal (congo red) stability (min) and hot deformation (%) as well as curing characteristics using different proportions of EDA were also examined. Physical properties of the EDA crosslinked and those of uncrosslinked PVC were studied and compared. Activation energy of EDA-induced crosslinking was 15 kcal/mol (63 kJ/mol). Crosslinking mechanisms have been discussed. (Author abstract). 21 Refs.

## Decomposition

**083834 TOXICITY OF THE PYROLYSIS AND COMBUSTION PRODUCTS OF POLY(VINYL CHLORIDES): A LITERATURE ASSESSMENT.** Poly(vinyl chlorides) (PVC) constitute a major class of synthetic plastics. This report reviews the literature published in English from 1969 through 1984 and endeavors to be more interpretive than comprehensive. PVC compounds, in general, are among the more fire resistant common organic polymers, natural or synthetic. The major products of thermal decomposition include hydrogen chloride, benzene and unsaturated hydrocarbons. In the presence of oxygen, carbon monoxide, carbon dioxide and water are included among the common combustion products. The main toxic products from PVC fires are

hydrogen chloride (a sensory and pulmonary irritant) and carbon monoxide (an asphyxiant). (Edited author abstract) 54 refs.

**Degradation** See Also HYDROGEN INORGANIC COMPOUNDS; IRON COMPOUNDS; POLYMERS—Antioxidants.

**083835 MECHANISMS OF ANTIOXIDANT ACTION: THE EFFECT OF SPIN TRAPS DURING THE PROCESSING AND PHOTOOXIDATION OF PVC.** It is demonstrated by the use of spin traps that during the early stages of thermal processing of PVC considerable concentrations ( $> 3 \times 10^{-6}$  mol g<sup>-1</sup>) of free radicals are produced which are primarily responsible for the initial products (hydroperoxides, unsaturation, and hydrogen chloride) previously shown to be formed in the polymer. From a semiquantitative analysis of these products, it is estimated that more than 50% of the radicals are formed from hydroperoxides and the rest by mechanoscion of the polymer chain. The spin traps are effective processing stabilizers in combination with a tin maleate HCl scavenger. One of them (2-methyl-2-nitroso propane, MNP) has also been shown to be a photoantioxidant. (Author abstract) 12 refs.

Adeniyi, J.B. (Aston Univ, Birmingham, Engl); Al-Malaika, S.; Scott, G. *J Appl Polym Sci* v 34 n 8 Dec 1987 p 2673-2679.

**083836 CATALYTIC EFFECT OF HCl ON THE DEHYDROCHLORINATION OF POLY(VINYL CHLORIDE).** Two poly(vinyl chloride) (PVC) samples with different thermal stability were degraded in both pure nitrogen and in an atmosphere containing HCl. The degradation experiments were made in a thermogravimetric system where the weight loss was measured. The polyene sequence distributions were monitored by UV-visible spectroscopy and the increase in the number of polyene sequences during degradation was measured by ozonolysis. The PVC sample with increased thermal stability showed less severe discoloration, i.e., the polyene sequences were shorter, when degraded in pure nitrogen. On the other hand when degradation was performed in an atmosphere containing HCl both the rate of dehydrochlorination and the polyene sequence length increased. (Edited author abstract) 24 refs.

Martinsson, E. (Chalmers Univ of Technology, Goteborg, Sweden); Hjertberg, T.; Soerik, E. *Macromolecules* v 21 n 1 Jan 1988 p 136-141.

**083837 INFLUENCE OF THE DEHYDROCHLORINATION RATE ON THE DEGRADATION MECHANISM OF POLY(VINYL CHLORIDE).** The degradation behavior of poly(vinyl chloride) (PVC) samples with considerably increased heat stability has been compared with that of an ordinary suspension PVC. The degradation rate was followed by measuring evolved HCl conductometrically. Structural changes in the polymer were monitored by several techniques: UV-visible spectroscopy was used to follow polyene sequences and gel permeation chromatography to detect changes in the molecular weight distribution and to determine the number of cleavages caused by ozonolysis, i.e., the number of polyene sequences. Besides decreased rate of dehydrochlorination the improved PVC samples become less discolored, i.e., the polyenes are shorter. The results obtained by ozonolysis and UV-visible spectroscopy show that this is because a lower number of HCl molecules is evolved from each initiation point. (Edited author abstract) 55 refs.

Hjertberg, T. (Chalmers Univ of Technology, Goteborg, Sweden); Martinsson, E.; Sorvik, E. *Macromolecules* v 21 n 3 Mar 1988 p 603-609.

**083838 PROBLEMS OF INTERACTION BETWEEN PLASTICISED PVC AND POLYURETHANE FOAM.** There are a number of applications of plasticized PVC where it is in contact with flexible or semiflexible polyurethane foam. In many instances the PVC has deteriorated at a faster rate than expected, the cause being the migration of plasticizers from the PVC into the PU. Of the various applications of PVC in contact with PU foam, the most technically demanding is car crashpads. The effect of PU additives on the thermal stability of PVC-based crashpad skins is the main subject of this paper. The aim of the research was to quantify the effects of different catalysts from the PU on a variety of plasticized PVC compounds under conditions of accelerated heat aging.

Wilson, A.S. (BP Chemicals Ltd); Bowley, H.J.; Gerrard, D.L. *Plast Rubber Int* v 13 n 1 Feb 1988 p 23-25.

**083839 THERMAL DEHYDROCHLORINATION AND STABILISATION OF POLY(VINYLCHLORIDE) IN SOLUTION; PART II-EFFECTS OF HCl READDITION REACTION.** The role of HCl during the thermal degradation of PVC has been investigated. It was shown that HCl catalyses the degradation as well as itself adding to the conjugated sequences in the degraded PVC. There is competition between these two reactions. At the beginning of the dehydrochlorination, the first reaction is dominant, while readdition becomes more important as double bonds are formed. Metal or organometallic chlorides may significantly influence these effects. The reverse reaction is catalysed by organotin chlorides of high Lewis acidity. These retardation effects are a pure consequence of the partial and random reversible thermal decomposition of PVC; they do not result from the configurational rearrangement by the readdition reaction nor by the internal isomerisation assisted by tin compounds. (Author abstract). 47 Refs.

Van Hoang, Tran (CNRS, Lyon-Vernaison, Fr); Guyot, A. *Polym Degradation Stab* v 21 n 2 1988 p 165-180.

**083840 SOLVATION STABILIZATION OF VINYL CHLORIDE POLYMERS TO DEGRADATION IN SOLUTION.** The rates of thermal degradation of vinyl chloride (VC) polymers in organic solvents and in the solid phase are significantly different. The kinetics of the process in the liquid phase is determined by the effects of specific and non-specific solvation interaction between the solvent and the polymer molecules. In the process of polymer degradation, solvation has different effects on the rate of random elimination of HCl from PVC with the formation of isolated C=C bonds and on the formation of poly-conjugated systems of double bonds. The rates of liquid-phase degradation of VC polymers in different classes of organic solvents are mainly determined by specific polymer-solvent solvation interaction; the overall dehydrochlorination rates of VC polymers in solution increase linearly with the basicity B (donor number  $D_N$ ) of a solvent: In addition to specific solvation, the rate of the liquid phase degradation of VC polymers in solvents is also affected by polymer-solvent non-specific interaction. The loosening of solvation interactions between polymer and solvent, resulting from addition of a non-polar hydrocarbon to the system, induces stabilization in solutions of VC polymers. (Author abstract). 8 Refs.

**083841 THERMAL AND THERMO-OXIDATIVE DEGRADATION OF POLYVINYL CHLORIDE IN PHOSPHORUS-CONTAINING PLASTICIZERS.** The kinetics of the degradation of PVC greatly changes on introducing phosphorus-containing plasticizers into the polymer system with a significant difference in the patterns of the processes of thermal and thermo-oxidative degradation. The main reason for the acceleration of thermodegradation of PVC in a medium of phosphorus-containing plasticizers is chiefly the high nucleophilicity of the esters of o-phosphoric acid governing the

specific solvation interaction between the molecules of the plasticizer and the polymer macrochains. The rate of the thermo-oxidative degradation of PVC plasticized by o-phosphates is determined by the reactivity of the esters of o-phosphoric acid in relation to oxygen. (Edited author abstract). 9 Refs.

**083842 USE OF LASER RAMAN SPECTROSCOPY TO STUDY THE DEGRADATION OF POLY(VINYL CHLORIDE).** The results of natural weathering tests carried out on plasticized poly(vinyl chloride) in three different locations representing cool/wet, hot/wet and hot/dry climates are detailed. The value of laser-Raman spectroscopy for determining dehydrochlorination levels of naturally weathered samples is demonstrated. The results indicate that plasticizers can play a significant role in this dehydrochlorination process. Results of studies on the effects of thermal stabilisers and amines, particularly those used as catalysts for polyurethane foam formation on the stability on poly(vinyl chloride) are also reported. (Author abstract) 30 refs.

## Dielectric Properties

**083843 DIELECTRIC PROPERTIES OF POLY VINYL CHLORIDE LOCAL FILLER BLENDS.** Dielectric properties of some PVC-local filler blends were investigated. Local calcium carbonate fillers from Mosul, Falloja and Karballa were used in this work. An imported filler, namely Ommya BSH was also used for comparison purposes. Dielectric constant, loss factor and loss tangent were measured by applying the following frequencies:  $10^{12}$ ,  $10^3$ ,  $10^4$  and  $10^5$  Herz at nine temperatures in the range of 21-150°C. Local filler blends appear to have dielectric properties comparable to the imported filler. Karballa filler blend exhibited lowest loss tangent property followed by Mosul, Ommya and Falloja. The results obtained indicate the suitability of using local fillers for the electrical cable insulation industry. (Author abstract) 7 refs.

## Diffusion

**083844 THEORY OF THE DIFFUSION OF LARGE MOLECULES IN AMORPHOUS POLYMERS ABOVE  $T_g$ .** A general theory of diffusion of large molecules in rubbery amorphous polymers is of interest for the scientific understanding and with regard to material design and process optimization. A broadly applicable model would be useful in developing controlled transport of plasticizers and other additives through polymeric substances. A diffusion model is presented which has been developed for large molecular penetrants above the  $T_g$  of the amorphous polymer allowing for required increase in redistribution of the free volume of the polymer structure, as well as the penetrant size and shape. Applicability of the model is demonstrated by comparing theoretically developed diffusion curves for DNOP and DNDP in PVC vs. their weight fractions at 82°C and 91°C. These theoretically derived plots are compared with experimental D vs.  $w_1$  curves for these systems generated at lower temperature. (Author abstract). 6 Refs.

## Dispersions

**083845 WLASCIWOSCI MICELARNE DYS-PERSJI EMULSYJNEGO PVC W PLASTYFIKATORACH.** [Micellar Behaviour of Emulsion-PVC Dispersions in Plasticizers]. The results of electrokinetic and rheological studies of emulsion-PVC dispersions in various primary plasticizers and in a composition of a primary and secondary plasticizer and a modifier have been presented. A series of factors influencing the value of  $\zeta$ -potential of a polymer particle in plastisol have been discussed, among others ionogenic impurities embedded in a PVC grain and derived from auxiliaries used in the vinyl chloride emulsion polymerization. It has been found that the particle charge increases with an increase in the solvation degree of PVC grain by plasticizer. A mechanism of the effect of a secondary plasticizer and modifier on the value of particle charge has been proposed. (Edited author abstract) 28 refs. In Polish.

Makarewicz, Edwin (Akad Techniczno-Rolnicza, Bydgoszcz, Pol). *Polimery* v 32 n 9 1987 p 364-368.

**083846 INTERACTIONS IN PVC-PLASTICIZER DISPERSIONS.** The properties of PVC plastisols depend on the interaction of the PVC particles in the plasticizer, which can be attributed to the formation of extended border layers at the particle surfaces. It is shown that this surface layer consists of a steric and an electrostatic component and its thickness can be varied within large limits. The contributions of both components are estimated, and a model of the surface layer structure is given. (Author abstract) 11 refs.

## Drawing and Stamping

**083847 ORIENTATION RELAXATION OF FLUORESCENT MOLECULES IN UNIAXIALLY DRAWN PVC-FILMS DURING ANNEALING.** PVC-films doped with fluorescent molecules of different shapes were uniaxially drawn at 65 and 80°C and subsequently annealed with free and fixed ends. The orientation behaviour of the fluorescent molecules and the polymer segments is investigated by UV-dichroism and fluorescence polarization and by birefringence respectively. The disorientation process of the fluorescent probes is shown to depend on drawing temperature and length of the probes. Longer fluorescent molecules lose their orientation more rapidly and shorter ones more slowly than the polymer segments on an average. (Author abstract) 8 refs.

## Electric Properties

**083848 PHOTOEXCITABLE POLYMER MEMBRANES. PHOTOINDUCED MEMBRANE POTENTIAL ACROSS POLY(VINYL CHLORIDE) MEMBRANE DOPED WITH A PHOTOSENSITIVE CROWN ETHER HAVING LIPOPHILIC SIDE CHAIN.** Photoirradiation induced potential changes of 10-20 mv across the poly(vinyl chloride) membranes doped with a photosensitive lipophilic crown ether, p-[3,4-(1,4,7,10,13-pentaoxaatridecane-1, 13-diyl)-phenylazo]hexadecyloxybenzene was studied. The photoresponse of the membrane was highly improved, presumably due to the lipophilic nature of the crown ether. The photoresponse was explained in terms of the charge density change on the membrane surface. The electric double layer theory was applied to estimate the values of the photoinduced change of the charge density. (Author abstract) 44 refs.

**Extrusion** See Also PIPE, PLASTIC—Mechanical Properties.

**083849 EVALUATION OF THE CAVITY TRANSFER MIXER FOR THE EXTRUSION OF RIGID PVC ON BOTH SINGLE AND TWIN SCREW EXTRUDERS.** PVC powder compound fed into single- and twin-screw extruders retrofitted with cavity transfer mixers improved PVC grain fusion. Consequent improvements in appearance and properties ought to reduce current tight compromises that must be made between materials costs, output rate, and quality. Impact testing was carried out using 50 mm square specimens cut from the center of the extruded strips (the edges being discarded) with a Gardner type variable height falling weight impact machine. A visual assessment was made of surface finish and general appearance, and the presence of secondary particles identified by optical microscopy using microtomed sections. (Edited author abstract) 5 refs.

**083850 NON-ISOTHERMAL FLOW OF RIGID PVC (POLYVINYLCHLORIDE) IN PLASTICATING EXTRUSION.** During the extrusion of rigid PVC (Polyvinylchloride) the slipping at the boundary, near the duct walls, has particular importance in avoiding the sticking of the polymer and the consequent chemical degradation. In the first part of this work a survey of the rheological characteristics of rigid PVC and the main features of the slipping effect at the wall are summarized. Afterwards the fluid dynamic behavior of the polymer in the metering zone of a single screw extruder is analyzed. The effects of viscous dissipation, of thermal boundary conditions and of slipping at the screw and barrel walls are numerically investigated using a suitable viscosity function to describe the shear-thinning behavior of the material. The influence of these parameters on the extruder characteristic curves (flow rate - back pressure gradient) is reported and the fluid dynamic regions where thermal degradation may occur are established. (Author abstract). 11 Refs.

## Fillers

**083851 EFFECT OF FILLERS ON THE IMPACT PROPERTIES OF OXYTUF HIGH IMPACT PVC.** Oxytuf mass polymerized PVC (IIP) contains grafted rubber moieties which provide for excellent impact resistance. The addition of a particulate filler to this resin with preservation of impact properties can be accomplished providing the particles are submicron and can be readily dispersed in the resin. Small particle size, surface treated, precipitated  $\text{CaCO}_3$ , when added to IIP provided impact retention superior to that of a homopolymer control containing an added, non-grafted impact modifier. (Author abstract) 9 refs.

## Film

**083853 DEVELOPMENT OF A MICRO (FTIR) SPECTROPHOTOMETRIC METHOD FOR CHARACTERIZATION OF HETEROGENEITIES IN POLYMER FILMS.** A method for characterization of heterogeneities in thin polymer films is developed. This method is based on micro (FTIR) spectrophotometry. The present paper describes the experimental procedure used to investigate the one dimension gradient of oxidation photoproducts in a poly(vinyl chloride) film (370  $\mu\text{m}$  thick) exposed to artificial accelerated weathering. (Author abstract) 6 refs.

Jouan, Xavier (CNRS, Aubiere, Fr); Gardette, Jean-Luc. *Polym Commun (Guildford Engl)* v 28 n 12 Dec 1987 p 329-331.

**083854 FLUORESCENCE METHOD FOR STUDYING SURFACE ORIENTATION OF POLYMER FILM USING VAUCCUM-DEPOSITION TECHNIQUE.** In order to establish a measurement for surface orientation of polymers, the fluorescence polarization method was applied for orientation analysis of fluorescent molecules vacuum-deposited on a polymer surface. The deposition behavior was also investigated. 1,6-Diphenyl-1,3,5-hexatriene (DPH) was deposited on the surface of poly(vinyl chloride) (PVC) films. The orientation behavior of DPH on vacuum-deposition was examined by the polarization of films, the orientation was found to be three-dimensionally random. After these fluorescent films were drawn above  $T_g$ , the surface orientation of the polymer chains was estimated by the dichroism of DPH, which was analyzed from the polarized components of fluorescence intensity. This system was compared with the DPH doped system in which DPH was distributed wholly in bulk. It was found that the orientation of DPH on the surface was slightly higher than that in the bulk. (Edited author abstract) 10 refs.

**083855 ID CARDS FROM PVC FILM.** The importance of the identity card has increased continuously in recent years and is expected to grow still further in the future. The majority of these cards are made of several layers of different PVC films. The construction of ID cards and their uses are described. (Author abstract) In German and English.

Bernatz, S.; Kaiser, L. *Kunstst Ger Plast* v 77 n 9 Sep 1987 p 28-29.

## Flammability

**083856 ASSESSMENT OF PVC SMOKE.** The physical problems are solved by material smoke production evaluation techniques based on apparatus, which has been developed by the National Bureau of Standards. A smoke parameter has been developed, calculated from cone calorimeter measurements, which reflects the smoke hazard of a real fire. The smoke evolution characteristics for a series of rigid thermoplastic materials have been measured using the cone calorimeter and the smoke parameter concept. The results demonstrate that due to its tendency to resist ignition and to burn very slowly, PVC would produce very little smoke in a real fire situation. Of the 15 materials tested, the expected real fire smoke performance characteristics of PVC were superior to those of all other materials except one. (Edited author abstract). 8 Refs.

Smith, Gregory F. (BF Goodrich Chemical Co, Avon Lake, OH, USA). *J Vinyl Technol* v 10 n 2 Jun 1988 p 84-89.

**083857 MODERATING THE SMOKE PRODUCED BY FLEXIBLE AND SEMI-RIGID PVC IN FIRE TESTS.** Flexible and semi-rigid PVC formulations with high oxygen indexes and low smoke densities, as measured by the NBS Smoke Test (ASTM E662-83) in both flaming and non-flaming modes have been identified. The feasibility of a significant reduction of HCl emission from PVC

compounds has been demonstrated in concept, and appears to be achievable when accompanied by increased oxygen index and/or significant reductions in rate of heat release and in smoke density, when measured in both the non-flaming and flaming modes. PVC compounds, including those incorporating the kind of improvements outlined here for experimental prototypes, may be expected to compete in the future in both performance and price compared to other plastics materials. (Author abstract). 15 Refs.

## Glass Transition

**083858 COMPOSITION DEPENDENCE OF THE GLASS TRANSITION TEMPERATURE OF POLYMER-DILUENT SYSTEMS: 1. EXPERIMENTAL EVIDENCE OF A DUAL BEHAVIOUR IN PLASTICIZED PVC.** The glass transitions of six PVC-diluent systems have been studied using differential scanning calorimetry (d.s.c.). The diluents were: di-(methyl, ethyl, n-propyl, n-butyl)-phthalate, n-butylacetate and tritolyl-phosphate. A large number of compositions have been examined over the whole concentration range, from pure polymer to pure diluent. For all systems two  $T_g$ /concentration dependencies can be identified: the fast decrease of the polymer  $T_g$  caused by plasticizer addition and the much slower increase of the diluent  $T_g$  due to the presence of the dissolved polymer molecules. (Edited author abstract) 11 refs.

Ceccorulli, G. (Centro di Studio per la Fisica delle Macromolecole, Bologna, Italy); Pizzoli, M.; Scandola, M. *Polymer* v 28 n 12 Nov 1987 p 2077-2080.

**083859 COMPOSITION DEPENDENCE OF THE GLASS TRANSITION OF POLYMER-DILUENT MIXTURES: 2. TWO CONCOMITANT GLASS TRANSITION PROCESSES AS A GENERAL FEATURE OF PLASTICIZED POLYMERS.** The available theoretical and empirical treatments concerning the glass transition temperature,  $T_g$ , of polymer-diluent mixtures do not account for the occurrence of the 'cusp' in the  $T_g$ /composition dependence or of the two concomitant glass transitions recently reported by the authors. The only treatment predicting a change of curvature in  $T_g$  vs. concentration, due to G. Braun and A.J. Kovacs, does not describe satisfactorily the behaviour of the seven polymer-diluent system is composed of two branches. It is concluded that in polymer-diluent mixtures still considered homogeneous at a macroscopic level two different mobilization phenomena occur, related to mobilization of 'hindered diluent' and 'plasticized polymer', respectively. (Edited author abstract) 24 refs.

## Heat Resisting

**083860 PUTTING THE HEAT ON HOUSING DESIGN.** Vinoflex G6173, 6184 and 80616 with respective Vicat softening temperatures of 78°, 74° and 81°C have been specially formulated with all the right properties: ease of flow; enhanced performance against heat deformation; and increased impact strength, to ensure that the company can capture a large share of this growing market. Prima has fire and chemical resistance with good weatherability and stability. Plascoat LSOH (low smoke zero halogen), based on polypropylene, eliminates the problems associated with most flame-retardant thermoplastics which contain halogen. A fireproof silicone composite, FPC, demonstrates its ability to withstand temperatures of up to 1000°C applied from one side for over 1 hour - and even higher temperatures for shorter periods.

Anon. *Eng Mater Des* v 32 n 6 Jun 1988 p 32, 34.

## Heat Stabilizers

**083861 STABILISATION OF PVC WITH ORGANOTELLURIUM COMPOUNDS.** Organotellurium compounds are shown to behave similarly to organotin compounds as thermal and UV stabilisers for PVC. The most effective of these, the dialkyltellurium maleates, were, however, less effective than the corresponding tin compounds but the study points the way to further progress in the design of organometallic compounds as PVC stabilisers. (Author abstract). 23 Refs.

Sbed-Ali, S.S. (Aston Univ, Birmingham, Engl); McWhinnie, W.R.; Scott, G. *Polym Degradation Stab* v 21 n 3 1988 p 211-225.

## Heat Transfer

**083862 STUDY OF THE THERMOPHYSICAL PROPERTIES OF MODIFIED POLYVINYL CHLORIDE.** The results of study of the heat conductivity, heat capacity and density of PVC modified with polyvinylbutyral and a phenol-formaldehyde resin are discussed. It is shown that the transitional layer takes part in the determination of the thermophysical properties of the composites of the polymer-polymer type. Analyzing the results of determination of  $\lambda_{eff}$  of the transitional layer of the PVC and PVB (Polyvinylbutyral) components and also the corresponding changes in the value of their densities we see that loosening of the PVC transitional layer with increase in the PVB content hampers heat exchange in the system. 10 refs.

**Impurities** See PLASTICS FILMS—Radiation Effects.

## Injection Molding

**083863 INJECTION MOLDING PVC.** Injection molding rigid PVC is no longer the chore it once was. Advances in resin properties, additive systems, and molding equipment have allowed injection molders to take advantage of PVC's favorable economic, weatherability, flame retardant, and chemical resistant properties. As a result, injection molding of PVC is entering a new era. With the proper equipment and formulations, today's PVC molder is graduating from pipe fittings to ever more profitable, yet demanding, parts and applications. (Author abstract) 6 refs.

Shaw, Lane G. (Air Products & Chemicals Inc, Allentown, PA, USA). *J Vinyl Technol* v 9 n 1 Mar 1987 p 2-9.

**083864 CORRELATIONS BETWEEN EXTRUSION AND INJECTION MOLDING PROCESS VARIABLES FOR PVC DRY BLENDS.** Although thermoplastic extrusion and injection molding have been extensively studied by a large number of authors, very little is known about the correlations between the extrusion and injection molding process variables. This paper describes the various comparable process variables between extrusion and injection molding of PVC dry blends. The Brabender extruder of 19 mm diameter and 25:1 length to diameter ratio and the Szekeley reciprocating single screw injection molding machine were used. PVC dry blends of industrial importance were prepared using a high speed mixer. The four mix formulations based on a commercial grade of PVC were used. Process variables studied during the injection molding were the melt temperature near the nozzle, injection pressure, injection speed, and energy consumption. (Edited author abstract) 16 refs.

Dalal, V.F. (Polytechnic of North London, London, Engl); Palit, K. *J Vinyl Technol* v 9 n 2 Jun 1987 p 86-90.

## Lubrication

**083865 STANDARDIZATION AND CONTROL OF PETROLEUM WAXES FOR RIGID PVC.** Methods are now available to determine the chemical composition

of petroleum waxes, control of which effectively governs the functional properties. By use of the analytical and property-related techniques of gas chromatography (GC) and differential scanning calorimetry (DSC), infinitely more precise compositional definition of a wax can be given, with potentially greater control of consistency and performance on a wax-to-wax, batch-to-batch basis. The article discusses the composition/characteristics of petroleum waxes. It also describes the DSC characterization of waxes. 4 refs.

Jowett, F. (Astor Wax Corp, Harrison, NY, USA). *Plast Compd* v 11 n 2 Mar-Apr 1988 4p.

## Manufacture

**083866 POLYVINYL CHLORIDE (PVC).** The development of the PVC market over the past four years has been characterised by capacity alignments and a steady, renewed increase in demand for PVC following the low of 1981/1982. The latent structural problems of excess PVC capacity in Western Europe led to the PVC producers shutting down capacity of 450 000 t/a over the period 1982 to 1986. According to the latest scientific findings, it may be assumed that the manufacture, processing, use and disposal of PVC and the articles made from it do not carry any health risks. Above this, production of this highly versatile plastic saves on resources, since 57% of the material in PVC is common salt, which occurs in abundance in nature, and only 43% comes from crude oil or natural gas. The liberation of hydrogen chloride from PVC when incinerated has no bearing on the ecology, since refuse incineration plants are required to be fitted with a waste gas scrubbing. 48 refs.

Birkner, H.; Neundorff, U. *Kunstst Ger Plast* v 77 n 10 Oct 1987 p 13-15.

**083867 GPSS SIMULATION OF PVC MANUFACTURE.** This paper describes a discrete-event analysis of batch production of PVC (polyvinyl chloride) using the GPSS computer simulation system. A number of different equipment configurations were examined in these simulations. Specifically, the number of polymerization reactors and the number of operators were varied. The effects of these changes on equipment and manpower utilization and on plant productivity were examined. In general, increasing equipment capacity and manpower led to increased productivity, but actual benefits of such changes must be evaluated with local economic factors. (Author abstract) 10 refs.

**Mechanical Properties** See Also PLASTICS—Elastoplasticity; VINYL RESINS—Crystallization.

**083868 EFFECT OF SMALL AMOUNTS OF CALCIUM CARBONATE ON MECHANICAL PROPERTIES OF RIGID PVC.** The effect of calcium carbonate in levels of 1 to 5 phr has been studied. Two types of calcium carbonate with an average particle size of 1 and 3 microns have been tested and for each formulation a graph has been drawn with drop impact strength as a function of mechanical processing at constant melt temperature. The maximum impact strength has been read from the graph. The results show that the content of calcium carbonate has an obvious effect on impact strength and that the effect of the fine-grained filler is clearly positive and that the effect of the coarse-grained filler is slightly negative. (Edited author abstract) 3 refs.

Bystedt, Jan (Norsk Hydro Plast AB, Stenungsund, Sweden); Erlandsson, Ann-Marie; Enequist, Bengt; Josefsson, Christina. *J Vinyl Technol* v 9 n 3 Sep 1987 p 136-139.

**083869 MECHANICAL PROPERTIES OF IMPLOSI-VELY COMPACTED SUSPENSION HOMOPOLYMER S 57/116 PVC POWDER.** The response of an aggregate of commercially produced particulate polymeric material to static and shock consolidation is described.

The presence of interparticle bonding, associated with the explosive process, considerably increases the strength and hardness of the compact, as compared with static processing, and enables a high degree of densification to be attained. The final properties of the compact are influenced by the initial particle size, tap density, and the characteristics of the container. For an aggregate varying in particle size from -150 to 212  $\mu$ m, optimal conditions are reached at shock pressures of between 10 and 11 GPa. (Author abstract) 12 refs.

**083870 MOLECULAR ORIENTATION AND YOUNG'S MODULUS OF PLASTICIZED AND NONPLASTICIZED POLY(VINYL CHLORIDE).** The Young's moduli of samples of poly(vinyl chloride) containing either no plasticizer or 5 phr of dioctyl sebacate were drawn uniaxially at 80°C to draw ratios,  $\lambda$ , in the range 1-3.3. The moduli, determined by a three-point bending method were found to increase monotonically with  $\lambda$  to a value of 6.3 GPa for the nonplasticized samples and to reach a maximum value of about 4.5 GPa for the plasticized samples above  $\lambda = 2.3$ , which showed voiding. The lower moduli of the plasticized samples for a given degree of orientation, as assessed from birefringence measurements, can be attributed to the diluent effect of the plasticizer on the load-bearing chains. The Raman measurements suggest that the crystallites probably orient rather like rigid rods in an affinely deforming matrix, with some relaxation. (Author abstract) 8 refs.

King, J. (Univ of Leeds, Leeds, Engl); Bower, D.I.; Maddams, W.F. *J Appl Polym Sci* v 35 n 3 Feb 20 1988 p 787-796.

**083871 CHANGE IN THE MECHANICAL PROPERTIES OF POLYVINYLCHLORIDE IN THE REGION OF THE BETA-TRANSITION.** The aim of this work is to elucidate the character of this dependence as illustrated by PVC in the region of the most considerable changes in the molecular mobility of glassy polymers - the region of the  $\beta$ -transition. It is shown that an increase in molecular mobility accompanying the  $\beta$ -transition must lead to some weakening of the intermolecular interaction. This conclusion follows from a phenomenon common to polymers as increase in the molecular mobility and fall in modulus as the temperature rises. It may be concluded that a correlation exists between the level of the molecular mobility and the elasticity modulus ion conditions of impact tests of PVC. The absence of such a correlation in the temperature dependence of the nominal elasticity modulus is explained by the fact that to fall in  $E_0$  corresponds increase in  $n$  and this mutually compensates their influence. 20 refs.

Kozlov, G.V. (Kabardino-Balkarsk State Univ, USSR); Shetov, R.A.; Mikitayev, A.K. *Polym Sci USSR* v 29 n 1 Jan 1988 p 68-74.

**083872 TENSILE, STRESS-STRAIN AND CREEP RUPTURE PROPERTIES OF POLY(VINYL CHLORIDE)/POLY(NEOPENTYL GLYCOL ADIPATE)/POLY(VINYLIDENE FLUORIDE) BLENDS.** Poly(vinyl chloride), PVC, and poly(vinylidene fluoride), PVDF, are incompatible polymers. Poly(neopentyl glycol adipate), PDPA, is miscible with both PVC and PVDF. With PDPA acting as a compatibilizer between PVC and PVDF, compatible PVC/PDPA/PVDF blends can be formed at PVDF content of about less than 50 wt percent. Above 50 wt percent PVDF the ternary blends exist in two phases exhibiting two glass transition temperatures,  $T_g$ . PVC is the main contributor to the mechanical strength while PDPA and PVDF contribute to the elastic properties of these blends. A compatible blend of 55/22.5/22.5

wt percent PVC/PDPA/PVDF exhibiting one single  $T_g$  appears to show an interesting balance of the properties of the blend components. (Author abstract). 12 Refs.

Lau, Wayne, W.Y. (Nat'l Univ of Singapore, Singapore); Swee-Hin, Teoh; Suat-Hong, Goh. *Br Polym J* v 20 n 4 1988 p 323-326.

**083873 MOLECULAR MODEL FOR TENSILE SHEAR BANDING AND THE BRITTLE-DUCTILE TRANSITION IN POLY(VINYL CHLORIDE).** Roebling's adaptation of the Ree-Eyring model to represent tensile shear banding of polymers in terms of two relaxation processes and Mansfield's model to describe alpha and beta relaxation processes in terms of polymer segment mobility are combined with the particulate structure of poly(vinyl chloride) (PVC) to give a more detailed connection between the macroscopic yielding process and the microscopic mobility of polymer segments. Mansfield's model for relaxation processes is cast in terms of intra- and inter-molecular interactions that serve to hinder orientational motions of polymer segments. The viscoelastic beta process in PVC is interpreted in terms of this model to be a hindered rotation of a segment about its main chain axis. About half of the activation energy of the beta process can be estimated from the barriers hindering rotation in simple alkyl halides. (Edited author abstract). 39 refs.

## Modification

**083875 STUDY OF THE POLYVINYL CHLORIDE-OLIGOETHER ACRYLATE SYSTEM BY THE PULSE NMR METHOD.** From the data on nuclear magnetic transverse relaxation the authors have derived information on change in the heterogeneity of the kinetic properties of molecules in the PVC-oligoether acrylate system at 20-175°C. Thermo-oxidative polymerization of oligoether acrylate in the polymer matrix is severely limited at a concentration of oligomer < 25 wt% proceeding much faster in the region 33-50 wt% than in the original oligomer and for a content of oligomer > 50 wt% in the same way as in the initial oligoether acrylate. Such specifics of oxidative polymerization in the absence of material initiators is predetermined by the character of the distribution of the temporary plasticizer in the system. (Author abstract) 20 refs.

**083876 CHEMICAL MODIFICATION OF POLY(VINYL CHLORIDE).** The aim of this paper is to review the literature on chemical modification of PVC. It is shown that PVC is an inherently unstable material both under the influence of heat and chemicals. The occurrence of undesirable side reactions, mainly dehydrochlorination, has been a persistent problem in the studies on the chemical modification of PVC. In most cases it has not been possible to prevent these side reactions from occurring, though their levels may have remained within

tolerable limits. There is some evidence of reactions and reaction conditions in which it has been possible to substitute a fair amount of chlorines in PVC by other functional groups without the occurrence of any significant level of dehydrochlorination. 196 refs.

**083877 PLANIRANI EKSPERIMENT KAO OSNOVA ZA OPTIMIRANJE MORFOLOSKIH SVOJSTAVA SUSPENZIJSKOG PVC-A.** [Statistically Designed Experiment as a Basis for Optimization of Morphological Properties of Suspension Polymerized PVC]. Porosity and particle size distribution, which define the suspension PVC morphological properties, are affected, among other things, by the type and concentration of suspending agents. The paper deals with the effect of cellulose products (HPC, HEC) and sorbitan monolaurate on the morphological properties of suspension PVC. In addition, the effects on other suspension PVC physical properties (K-value, bulk density, flowability, plasticizer absorption rate) are also shown. By employing statistical design of experiments, testing time and cost has been reduced and test efficiency increased. (Edited author abstract) 26 refs. In Serbo-Croatian.

**083878 INFLUENCE OF THE MORPHOLOGICAL STRUCTURE OF THE MATRIX ON THE REGULARITIES OF IMPACT FRACTURE OF POLYVINYL CHLORIDE MATERIALS.** The influence of the morphological structure of PVC and of its compositions with elastomers on the work of fracturing has been studied over a wide range of loading rates with stretching. The relation of the specific surface of the initial polymer powder to the nature of rate dependence of the work of fracturing has been demonstrated. Some possibilities of enhancing the impact strength of PVC materials by increasing the degree of heterogeneity of their structure have been established. (Author abstract) 10 refs.

## Optical Properties

**083879 OPTICAL PROPERTIES OF CONJUGATED SEGMENTS EMBEDDED IN POLYVINYLIDENE-CHLORIDE.** Oriented conjugated segments embedded in polyvinylidene-chloride (PVDC) were prepared by thermal degradation of PVDC-films under applied mechanical stress. These samples exhibit stable optical properties while stored in air in contrast to the oxidative instability of pure polyacetylene. Transmission spectra in the visible range show highly anisotropic properties even at low concentration of conjugated bonds. Distinct oscillatory behavior of the absorption of light polarized perpendicular to the stretching direction is observed and the positions of the extrema are extrapolated to infinite conjugation length assuming a simple model. A comparison with optical data for dense trans-(CH)<sub>x</sub> films yields an average conjugation length of  $n=36$  for oriented crystalline trans-(CH)<sub>x</sub>-films and  $n=11-14$  for amorphous trans-(CH)<sub>x</sub> films. (Author abstract) 12 refs.

## Oxidation

**083880 INVESTIGATION OF THE ROLE OF POLYENES SEQUENCES IN THE THERMAL OXIDATION PROCESS OF POLY(VINYL CHLORIDE).** UV-visible absorption spectrophotometry was used to

study the discoloration of thermo-oxidatively treated PVC samples at 110°C. Degraded PVC films show characteristic absorption spectra with absorption maxima at 388, 415, 441, 462 and 485 nm. The optical density of these five absorption maxima increased with time of thermal aging. Differential scanning calorimetry (DSC) was used to study the melting behaviour of polyene containing predegraded PVC samples. The melting temperature of predegraded PVC samples increased with the increase of thermal treatment. (Author abstract) 18 refs.

## Phase Diagrams

**083881 MECHANISM OF FORMATION OF THE DISPERSE PHASE STRUCTURE OF POLYMER MIXTURES DURING TRANSITION FROM TERNARY (POLYMER-POLYMER-SOLVENT) TO BINARY (POLYMER-POLYMER) SYSTEMS.** The disperse phase structure of the binary PVC-PMMA system, formed from PVC-PMMA-THF solutions, has been studied quantitatively. A phase diagram of the ternary system was obtained. It was discovered that the binary system is formed in a region of the ternary phase diagram far from the polymer-polymer equilibrium. Stabilization of the phase structure of the mixture occurs in that region of the ternary diagram where a sharp increase in the viscosity of the system occurs, due either to phase- or relaxation transitions. The observed phenomenon has a general importance for systems of limited compatibility prepared from solutions. (Author abstract) 15 refs.

Chalykh, A.Ye. (USSR Acad of Sciences, USSR); Sapozhnikova, I.N.; Medvedeva, L.L.; Gerasimov, V.K. *Polym Sci USSR* v 28 n 9 1986 p 2108-2115.

## Phase Transitions

**083882 OBSERVATION OF A SUB(gel-sol) TRANSITION IN PVC/DOP GELS.** Dynamic viscoelastic measurements on poly(vinyl chloride)/dioctyl phthalate gels have been carried out in parallel-plate shear mode. Two transitions are observed: the well-known gel-sol transition at temperature  $T_g$ , which probably corresponds to the beginning of fusion of crystallites, and a transition, at a temperature below  $T_g$ , denoted as  $T_s$  and corresponding to phase separation. The sub(gel-sol)  $T_s$  temperature is manifested as the transition from the first plateau zone to a second plateau in log  $G'$  versus temperature plots. Other techniques like polarizing microscopy and DSC measurements are not adequate for the detection of  $T_s$ . (Author abstract). 22 Refs.

## Photochemical Reactions

**083883 PVC COMPOUNDS FOR PHOTOCHEMICAL CROSSLINKING.** The best of all photoinitiator systems for crosslinking PVC compounds, according to tests made with a Tesla RVIM discharge tube, is the combination of chlorthioxanthone and triethanolamine. Pentaertholthriacrylate is the most effective crosslinking agent. Lead stabilizers give the best heat stability and a higher rate of a photochemical crosslinking than tin and antimony stabilizers. (Author abstract) 9 refs.

**083884 THERMAL ANALYSIS IN STUDIES OF PHOTOCHEMICAL TRANSFORMATIONS IN PVC.** The effects of photochemical processes in PVC in response to UV irradiation at 253.7 nm on its thermal stability were investigated. It was found that small

differences in the efficiency of the photochemical processes taking place in the PVC can be recorded in the thermal measurements, and that photodehydrochlorination lowers the temperature of thermal dehydrochlorination, while photooxidation and crosslinking increase the temperature of complete decomposition of this polymer. (Author abstract) 20 refs.

**Physical Properties** See Also ORGANIC COMPOUNDS—Synthesis; POLYMERS—Physical Properties.

**083885 PHYSICAL GELS FROM POLY(VINYL CHLORIDE): BEHAVIOUR WITH CONCENTRATION AND TEMPERATURE OF AGGREGATES FORMED IN DILUTE SOLUTIONS.** Aggregates formed in dilute poly(vinyl chloride) (PVC) solutions (i. e. below the critical gel concentration) have been studied by static and quasielastic light scattering as well as by viscometry as a function of the polymer concentration and the temperature. From the results, it is concluded that two types of physical links exist in these aggregates: 'strong' links that persist up to 62°C and 'weak' links that progressively break up with temperature. Further, the weak links are absent in aggregates prepared at the lowest concentrations ( $C \leq 0.5 \times 10^{-2} \text{ g cm}^{-3}$ ) but appear at the highest concentrations ( $C \geq 1 \times 10^{-2} \text{ g cm}^{-3}$ ). These results are discussed and the conclusions are extrapolated to the gel state. In particular, it is suggested that the weak links are responsible for the physical ageing of PVC thermoreversible gels. (Author abstract) 17 refs.

## Polymerization

**083886 APPLICATION OF AN EXPERT SYSTEM AND INDIRECT MODEL IN PVC INDUSTRIAL BATCH REACTOR.** PVC is one of the important materials in the modern society. The qualities of PVC depends on the constancy of the reacting temperature to a great extent. However, the polymerized process of a PVC reactor is a highly nonlinear and time-varying process. It is difficult to control the temperature of the reactor. In this paper a multistage cascade control corrected algorithm with an expert system and indirect control model is proposed. (Edited author abstract) 8 refs.

Wu, Qibin (Qingdao Inst of Chemical Engineering, China); Qi, Shufen; Liu, Chuanlai. *Modell Simul Control B* v 13 n 2 1988 p 55-63.

**083887 INFLUENCE OF POLY(VINYL ALCOHOL) SUSPENDING AGENTS ON SUSPENSION POLY(VINYL CHLORIDE) MORPHOLOGY.** After a brief review of the mechanism of PVC suspension polymerisation, the properties of polymers made using PVOH suspending agents are related to changes in the latter. The effect of variations in PVAc degree of hydrolysis and viscosity are related to changes in surface tension. Methods of achieving higher porosity by using low hydrolysis co-suspending agents are described. It is shown that higher bulk densities can be achieved by delayed addition of the PVOH. Levels of conjugated unsaturation and copolymer distributions are also shown to have important influences. (Edited author abstract). 14 Refs.

**Processing** See Also COPOLYMERS—Processing; PIPE, PLASTIC—Manufacture; PLASTICIZERS—Applications; WATER PIPELINES—Plastics Applications.

**083888 GEL PHENOMENA IN FLEXIBLE PVC RESIN.** The existence of fisheyes or gels in PVC final products has been a problem which the PVC industry has coped with for many years. The classical gel is a non-porous PVC particle which cannot adsorb plasticizer.

Other finished product defects which may be classified as gels by a customer are unfused particles of higher molecular weight resin or resin gels and agglomerates caused by improper mixing procedures called compound gels. Although this paper will define and cite examples of resin gels and compound gels, it will deal primarily with classical gel. Over the years, many different gel tests have been used by PVC suppliers and consumers in order to define the gel level of a particular sample of resin. The most common of these tests is the test using a two roll mill to produce a colored mill sheet which is examined and the number of gels reported. (Edited author abstract) 4 refs.

**083889 PROCESSING AIDS FOR CHLORINATED POLYVINYL CHLORIDE.** Comparative studies of melt processability showed that chlorinated polyvinyl chloride (CPVC) had low melt index and high Brabender melt temperature and torque, as compared with conventional rigid polyvinyl chloride (PVC). Of 3 processing aids at 10 percent concentration, triphenyl phosphate increased melt index 30-fold, fusion rate 10-fold, melt temperature 20°C, and torque 31 percent in CPVC. Two other processing aids, an acrylic and a styrene/acrylonitrile copolymer, were less effective. Improvements in PVC were less dramatic than in CPVC. Overall, use of processing aids made CPVC processability equal or even superior to conventional rigid PVC. (Author abstract) 18 refs.

Deanin, Rudolph D. (Univ of Lowell, Lowell, MA, USA); Mast, Jonathan D. *J Vinyl Technol* v 9 n 1 Mar 1987 p 15-17.

**083890 EFFECT OF TYPE AND CONCENTRATION OF PLASTICISER ON BEHAVIOUR OF PVC. PART 2: PROCESSING.** PVC compounds containing 30, 50 and 70 phr of various plasticizers were dry blended then processed at temperatures in the range 150°C to 200°C in a Banbury mixer. Temperature profiles obtained during dry blending were interpreted in terms of physical changes in the dry blend. Rapid plasticizer uptake resulted in grain swelling which was then followed by grain attrition. Surface mattness tended to disappear at high plasticizer concentration, high Banbury processing temperatures, and when more active plasticizers were used. (Edited author abstract) 16 refs.

**083891 POLY(VINYL CHLORIDE)/PLASTICIZER-MIXTURE INTERACTIONS. PART I. PHTHALATE ESTER MIXTURES.** Flory-Huggins interaction parameters,  $\chi$ , have been determined as a function of plasticizer composition for poly(vinyl chloride) in various binary mixtures of phthalate ester plasticizers using a method involving the micro-determination of the temperature at which PVC particles in excess plasticizer appear to melt. An optimum composition at which  $\chi$  goes through a minimum was found to exist for some of the systems. A good correlation between the apparent melting temperature and  $\chi$  for the neat plasticizers with PVC was also established. (Edited author abstract). 7 Refs.

Tomaselli, F. (Carlew Inc, St.-Remi, Can); Gupta, V.P.; Calderon, H.S.; Brown, G.R. *J Vinyl Technol* v 10 n 2 Jun 1988 p 72-76.

**083892 APPLICATION OF THE UNIFAC-FV GROUP CONTRIBUTION METHOD TO THE PREDICTION OF RELATIVE COMPATIBILITY OF PLASTICIZERS WITH PVC.** The applicability of a modified version of UNIFAC group contribution method, UNIFAC AC-FV, is explored for use in predicting liquid-liquid equilibrium behavior of plasticizer/PVC systems. A Fortran program for the UNIFAC-FV model has been written to calculate the activities and changes in the Gibbs free energy for multicomponent systems. By this means, the interaction parameter  $\chi$  for a polymer-solvent system is defined using the well known Flory-Huggins

equation. The concentration dependent Gibbs free energy of mixing is used as a criterion for the relative compatibility of the PVC-plasticizer system. The method indicates that, for the plasticizers examined, DOS is the least compatible and DBP is the most compatible with PVC. This confirms the results of the glass transition width measured by dynamic mechanical analysis previously reported. (Author abstract). 19 Refs.

## Production

**083893 RECENT DEVELOPMENTS IN PVC POLYMERIZATION.** The report concentrates on those aspects of vinyl chloride (VCM) polymerization where recent work has provided us with a better understanding or new insight. The progress in the field made during the last few years is mainly due to the fact that new or strongly improved experimental techniques (e.g., more powerful spectroscopic methods) have become available. Besides a discussion of recent work in the field, the present contribution gives a brief, general introduction to PVC and a short description of the main polymerization processes used for PVC production. This will serve mainly as a background for those who have not been active in the field. 54 refs.

**Pyrolysis** See Also POLYSTYRENES—Degradation.

**083894 PRODUCTS OF NON-FLAMING COMBUSTION OF POLY(VINYL CHLORIDE).** A relatively large laboratory-scale sample of a commercial type of poly(vinyl chloride) usually used for window blinds, was decomposed by non-flaming combustion under carefully controlled conditions (823, 1023 and 1223 K, in air, in a mixture of air and nitrogen and in nitrogen) which simulated the main stages of development of a fire. Three fractions of the decomposition products, residue, gases and organic volatile-condensable products, and the influence of the decomposition conditions on their yield, were studied. The residue yield decreased with increase in the decomposition temperature and in oxygen content of the atmosphere. The organic volatile-condensable products consisted mainly of aromatic compounds many of which contained fused rings. Benzene was the dominant product in this fraction. (Edited author abstract) 24 refs.

## Quality Control

**083895 SQC IN PVC QUALITY CONTROL TESTING.** Quality control testing can be improved by applying statistical methods. For example, control testing of resins at different locations can identify idiosyncrasies in sites as well as in the testing itself. A program using standard and 'control' resins in round-robin testing between sites was designed to find the sources of variability and to develop procedures to reduce it. The test procedures were: inherent viscosity, bulk density, dry contamination, fisheyes, dry-blend time, particle-size distribution, and PVC resin color. Statistical quality control (SQC) charting with root-cause analysis identified mechanical, environmental, and procedural sources of variability. (Edited author abstract) 3 refs.

**Radiation Effects** See Also DOSIMETERS—Plastics Applications; MEMBRANES—Radiation Effects.

**083896 CHEMICAL CHANGES IN ELECTRON-BEAM-IRRADIATED POLYMERS.** It is shown that the unzipping mechanism could be particularly important for the initial stages of dehydrochlorina-

tion of the irradiated polymer and thus for the explanation of the double exponential decay curves. The analysis of IR spectra is not very easy and only recently has Fourier Transform Infrared (FTIR) spectroscopy with powerful facilities become available. The purpose of this work is to utilize the FTIR spectroscopy for the study of chemical changes in chlorinated polymers, mainly PVC and to correlate the results with chlorine loss curves, measured by X-ray energy dispersive analysis. 21 refs.

Vesely, D. (Brunel Univ, Uxbridge, Engl); Finch, D.S. *Ultramicroscopy* v 23 n 3-4 1987 p 329-337.

**083897 IMPROVEMENT OF PVC FLOOR TILES BY GAMMA RADIATION.** Gamma radiation presents a unique method of transforming highly plasticized PVC floor tiles, manufactured at high speed through injection moulding, into a high quality floor covering at a cost at least 30% less than similarly rated rubber tiles. A specially formulated PVC compound was developed in collaboration with a leading manufacturer of floor tiles. These tiles are gamma crosslinked in shipping cartons to form a dimensionally stable product which is highly fire resistant and inert to most chemicals and solvents. These cross-linked tiles are more flexible than the highly filled conventional PVC floor tiles, are scratch resistant and have a longer lifespan and increased colour fastness. These tiles are also less expensive to install than conventional rubber tiles. (Author abstract) 8 refs.

## Recycling

**083898 RECYCLING OF WASTE PVC LEATHER AND PVC URETHANE IN THE AUTOMOBILE INDUSTRY.** Waste plastics are low in scrap value in the automobile industry and are most difficult to dispose of for reutilization. The waste plastics have been disposed of by incineration and reclamation as measures for preventing industrial pollution, but these measures involved various problems and quite a different idea could be successfully developed to effectively reutilize them. The case of reutilization is introduced here. (Author abstract)

## Research

**083900 ROLE OF THE EMULSIFIER IN THE FORMATION OF AN ELECTRIC DOUBLE LAYER ON PARTICLES OF POLYVINYL CHLORIDE IN PLASTISOLS.** The role of an ionogenic emulsifier in the formation of an EDL on particles of polyvinyl chloride (PVC) in plastisols was determined. It was shown that the emulsifier is partially desorbed from the surface of the polymer into the plasticizer and is ionized in the plasticizer. The effect of the concentration of the emulsifier in the plasticizer on the value of the  $\zeta$  potential of the polymer particles was studied. It was found that dissociation of the emulsifier in the plasticizer determines the electrical conductivity of the dispersion medium of plastisols and consequently the thickness of the electric double layers (EDL) on the PVC particles. (Edited author abstract) 13 refs.

*USSR* v 49 n 1 Jan-Feb 1987 p 1-6.

**083901 THEORETICAL STUDY OF PREPARATION OF PLASTICIZED PVC SAMPLES EXHIBITING LOW MATTER TRANSFERS.** A method of preparation of plasticized PVC sample exhibiting very low levels of mass transfer when contacted with a liquid was studied from an experimental and theoretical point of view. The principle of the method was as follows: The sample was soaked in the liquid for a definite short time and two matter transfers took place; the liquid entered the PVC while the plasticizer left the PVC. Then the sample was extracted and the liquid located in the PVC was evaporated. Both these transfers were found to be controlled by transient diffusion with concentration-dependent diffusivities. A model based on numerical methods with finite differences was developed and successfully tested. (Edited author abstract). 21 refs.

**Rheology** See Also PLASTISOLS—Physical Properties; RHEOMETERS—Applications.

**083902 RHEOLOGY OF PVC.** A brief historical review has been made of rheological instrumentation developed for measuring the flow properties of vinyl materials. During this maturation of techniques the need for more complete flow characterizations spawned the development of dynamic mechanical instruments. These instruments provided convenient and accurate means of generating complex viscosity data composed of elastic and elements. Examples have been presented illustrating how these newer techniques are able to reliably provide critical data needed to control productivity and product performance properties. Extension of these techniques to on-line rheometry has improved quality control link in the compounding operation. (Edited author abstract)

## Stabilizers

**083903 EFFECT OF BARIUM AND CADMIUM STABILIZERS ON THE THERMAL DEHYDROCHLORINATION OF POLY(VINYL CHLORIDE): A RESONANCE RAMAN SPECTROSCOPIC STUDY.** A laser Raman spectroscopic study has been made of the effect of barium and cadmium stabilizers on the thermal dehydrochlorination of poly(vinyl chloride)(PVC). The results obtained indicate that, in terms of the total level of dehydrochlorination, cadmium stearate is not as superior to barium stearate as the visual appearance of the polymer suggests. Also, the level of dehydrochlorination produced in the presence of a mixed stabilizer is not significantly lower than that produced in the presence of barium stearate alone, while samples of the latter exhibit much stronger color. It has also been shown that cadmium stearate can reduce the length of long polyene sequences, presumably by a reaction near the center of such a sequence. (Author abstract) 8 refs.

Gerrard, D.L. (BP Research Cent, Sunbury-on-Thames, Engl); Bowley, H.J.; Biggin, I.S. *J Vinyl Technol* v 9 n 2 Jun 1987 p 43-45.

**083904 STABILIZATION OF POLY(VINYL CHLORIDE). VIII. SYNERGISMS BETWEEN EPOXY COMPOUNDS AND METAL SOAPS.** Effects of bisphenol A type epoxy compounds involving various average molecular weights on the zinc stearate/calcium stearate and the cadmium stearate/barium stearate synergistic soaps induced thermal stabilization of poly(vinyl chloride) (PVC) were investigated by colorimetry. The remarkable stabilization effects of epoxides could not be observed on the PVC films without synergistic soaps, while

the stabilization of PVC was markedly enhanced by combined use of epoxides and synergistic soaps. The appearance of excessive coloration of cool color producing metal chloride-polyene complexes which were an origin of abrupt discoloration of stabilized PVC was retarded by using epoxides together with synergistic soaps. (Edited author abstract) 18 refs.

Iida, Takeo (Osaka Inst of Technology, Osaka, Jpn); Kawato, Junji; Maruyama, Kazushige; Goto, Kunio. *J Appl Polym Sci* v 34 n 7 Nov 20 1987 p 2355-2365.

**083905 PVC STABILISERS.** In Western Europe, 34 companies are suppliers of PVC heat stabilisers; eighteen of these are engaged in manufacturing and development. Solid stabilisers are utilised in the processing of rigid PVC while liquid stabilisers are used for plasticised PVC and pastes. Consumption of stabilisers in Western Europe in 1987 is estimated at some 87000 t. Of this 56000 t (64%) will be for processing of rigid PVC and 31000 t (36%) for processing of plasticised PVC and pastes. The product development of PVC stabilisers must be considered in the light of the growth of PVC consumption. Although the heat stabilisation of PVC has achieved a high technical standard, innovations are still sought in areas where disproportionate growth is predicted. Toxicological reservations and environmental compatibility requirements are further reasons for increased activity in product development. Based on forecasts for PVC for the next years, it is safe to say that the stabiliser market will remain steady. There will be a shift to increased lead content. 11 refs.

Goerlich, E. *Kunstst Ger Plast* v 77 n 10 Oct 1987 p 87-88.

**083906 PROTON DONORS AS STABILIZERS FOR POLYVINYL CHLORIDE.** The chemical stabilization of PVC by proton donors such as carboxylic, hydroxyl and CH acids has been examined. The stabilizing action of these compounds was examined from the viewpoint of their interaction with active centers of PVC thermal degradation i.e. with grouping such as  $-(CO)-CH=CH-CHCl-$ . The correlations of the relation between the magnitudes of the stabilizing effect of proton donors and their activity have been established. Compounds of high acidity have a large inhibiting action of the thermal degradation of the polymer. (Author abstract) 6 refs.

Kolesov, S.V. (USSR Acad of Sciences, USSR); Steklova, A.M.; Ge, M.; Zaikov, G.Ye.; Minsker, K.S. *Polym Sci USSR* v 28 n 9 1986 p 2096-2103.

**083907 SYNERGETIC EFFECTS OF POLYACRYLATES WITH SYNERGETIC METAL SOAP ON THE STABILIZATION OF POLY(VINYL CHLORIDE).** Effects of synergistic combination of polyacrylates and zinc stearate/calcium stearate soap on the thermal stabilization of poly(vinyl chloride) (PVC) were investigated by colorimetry. Poly(sodium acrylate), poly(methyl acrylate), and poly(ethyl acrylate), and partially saponified poly(methyl acrylate) and poly(methyl methacrylate) markedly enhanced the thermal stabilization of PVC containing zinc stearate/calcium stearate soap, while poly(acrylic acid), poly(butyl acrylate), poly(2-ethylhexyl acrylate), and poly(methyl methacrylate) did not exhibit measurable enhancement of the stabilization of PVC. The synergism of polyacrylates with the synergistic metal soap was enhanced with decreasing number of carbons in the side chains, and this was due to good compatibility of the polyacrylates having shorter side chains with PVC. X-ray photoelectron spectroscopy of the polyacrylates-metal soap-PVC mixture indicated that the polyacrylates, which were effective as co-stabilizer, formed Zn-O linkages with zinc chloride. (Edited author abstract) 15 refs. In Japanese.

## Strain

**083908 STUDY OF RABOTNOV'S EQUATION AND ITS APPLICATION TO POLYMER MATERIALS.** A method of independent definition of functions appearing in Rabotnov's equation is suggested; it is based on experimental isochronic curves of creep. It is shown that the equation can be applied uniformly to monotonic and nonmonotonic time variations of strain. The equation predicts an accelerated recovery, compared with the Rozovsky-Persault equation. Rabotnov's equation is shown to describe adequately the results of experiments with polyvinylchloride and polymethyl methacrylate under constant loads and when subjected to step loading. ## Synthesis

**083909 POLYMERIZATION OF VINYL CHLORIDE AT REDUCED MONOMER ACCESSIBILITY. IV. THE EFFECT OF DIFFUSION CONTROL ON POLYMERIZATION RATE, MOLECULAR WEIGHT, AND THERMAL STABILITY.** The effect of diffusion control on the polymerization of vinyl chloride has been studied by observing the rate as well as the molecular weight and the thermal stability of the polymer formed. The polymerizations were performed at 97% of saturation pressure in a water-suspended system at 55°C, using emulsion PVC latex as seed and a water-soluble initiator. The monomer was charged as vapor from a storage vessel kept at a lower temperature. Characterization included determination of molecular weight distribution by GPC and viscometry, and thermal dehydrochlorination. The gas-liquid contact was varied by changing the speed of agitation and the design of the stirrer. With a propeller, the polymerization rate increased with the agitation up to ca. 1000 rpm, where after it became almost constant. Simultaneously, the molecular weight and the thermal stability increased. (Edited author abstract) 21 refs.

**083910 TENSILE CREEP TESTS, INTERNAL PRESSURE TESTS, AND SCANNING ELECTRON MICROSCOPY OF ELECTRICAL CONDUITS OF POLY(VINYL CHLORIDE).** Electrical conduits prepared from a mixture of suspension and emulsion poly(vinyl chloride) (PVC) resins were subjected to internal pressure tests at 60°C, covering a wide range of pressures. Some axial tensile creep tests were also carried out at the same temperature. As expected, the ability to withstand internal pressure decreased when the amount of lubricant was increased above the level used in normal commercial production. Fracture surfaces obtained in the two test methods were investigated by scanning electron microscopy. (Edited author abstract) 6 refs.

## Thermal Effects

**083911 EFFECT OF SELECTED PIGMENTS ON HEAT BUILD OF RIGID PVC SIDING.** The concept is that high-IR-reflecting pigments can be effective in reducing heat build of plastics subjected to solar exposure and that this should translate into improved physical-property retention and reduced buckling due to thermal expansion. Data are given for a high-IR black pigment in gray, pastel, and brown vinyl siding. This article will show how effective a high-IR-reflecting black pigment can be compared to other typical blacks in reducing heat build in gray, pastel, and brown rigid PVC

house siding.

## Viscoelasticity

**083912 COMPLEX PLANE PARAMETERS FOR THE VISCOELASTIC BETA PROCESS IN POLY(VINYL CHLORIDE).** Tensile-yield studies show that the high strain rate or low temperature behavior of poly(vinyl chloride) may be determined by its beta process. In this work we made viscoelastic measurements covering the beta process over a temperature range of -140 to 20°C and a frequency range of 0.1-30 Hz. The activation energy for the beta process was found to be  $14.1 \pm 1.2$  kcal mol<sup>-1</sup> which is in excellent agreement with the value of 14 determined from tensile yield studies. The  $\alpha$  and  $\beta$  parameters for the relaxation function are discussed in terms of Mansfield's spring and dashpot model representing intra- and intermolecular interactions. (Edited author abstract) 12 refs.

## Waste Disposal

**083913 PVC AND INCINERATION.** Among the most feared toxic chemicals known to man is 2,3,7,8-tetrachlorodibenzodioxin (TCDD). PVC is a source of chlorine in waste and therefore it has been contended that its means of disposal should not be incineration. It is argued that the chlorine content of non-PVC sources is in excess of that needed for dioxin production and therefore exclusion of PVC from municipal waste will have little effect upon harmful emissions. This investigation presents evidence substantiating this concept. (Author abstract). 19 Refs.

**Weathering** See Also BUILDINGS—Facings.

**083914 WEATHERABILITY OF POLYVINYL CHLORIDE.** When PVC is exposed to long-term outdoor environment, it undergoes very slow long-term photochemical degradation. It is subjected to various atmospheric effects including exposure to rain, fungus, mechanical stress pollutants and exposure to ultraviolet radiation. The ultimate result is then reflected in a marked loss of plasticizer, discoloration, embrittlement and finally loss in mechanical properties. The problem, therefore, concerns the photochemical instability even at a much lower temperature which severely restricts the use of resin in outdoors where long-term performance is of prime importance. The authors present the current trend of research in the field of photostabilization of PVC during outdoor weathering. 72 Refs.

## Welding

**083915 RELATIONSHIP OF WELDING TECHNOLOGY TO DEGREE OF PLASTICIZATION IN THE PVC FILMS.** The influence of the degree of plasticization on optimum heat-sealing or high-frequency welding conditions has been studied for plasticized PVC films with different quantities of DOP plasticizer. Two equations were obtained that relate the parameters of the welding process (time and temperature, or time and specific anodic current) with the degree of PVC film plasticization. The equations allow calculation of welding conditions needed to obtain maximum strength of welded joints. One describes the durability of lap joints; the other

of T-joints. (Author abstract) 5 refs.

## Blending

**083916 MORPHOLOGICAL STUDY OF PVDC/PE BLENDS.** Polyvinylidene chloride copolymers (PVDC)/polyethylene (PE) immiscible blends offer improved extrusion processing over PVDC alone while retaining the excellent oxygen and water barrier properties. The transport of permeants through these composites is related to the geometry of the dispersed phase PE. A lamella or striated type PE phase is desired as this results in a better barrier than a more spherical geometry. This morphology can originate most easily from extensional flow. Other possible mechanisms to consider are the relationship of normal and surface tension stresses, and the breakup and coalescence equilibrium of the dispersed phase. (Author abstract) 9 refs.

**083917 GENERALIZED PROBABILITY MODEL FOR ESTIMATING THE PROPORTION OF THE FEMALE POPULATION AT DIFFERENT LEVELS OF FERTILITY BASED ON CENSUS SAMPLING FROM A MIXED POPULATION.** The present exercise is an attempt to generalize a probability model referring to the waiting time distribution for conception in a mixed group of fecund females with two varying levels of fecundity, based on a census sample truncated at time  $T = t$  from the date of resumption of fecundity following an earlier conception. Estimates of the proportion of fecund females over time, viz.,  $\pi_i(t)$  ( $i = 1, 2, 3$ ) are attempted by the method of maximum likelihood on the basis of a census sample truncated at time  $T = t$  under the generalized set up. (Edited author abstract) 6 refs.

Biswas, Suddhendu (Univ of Delhi, Delhi, India); Kumar Sehgal, Vijay. *Int J Syst Sci* v 18 n 10 Oct 1987 p 1909-1917.

**083918 CHAOS AND THE DYNAMICS OF BIOLOGICAL POPULATIONS.** As first emphasized in the early 1970s, the nonlinearities that are inherent in simple models for the regulation of plant and animal populations can lead to chaotic dynamics. This review deals with a variety of instances where chaotic phenomena can arise, particularly in interactions between prey and predators (including hosts and pathogens, hosts and parasitic insects, and harvested populations). Some of the complications in disentangling deterministic chaos from environmental noise will be discussed. The combination of population biology with population genetics leads to an even richer assortment of nonlinear phenomena and to the suggestion that many genetic polymorphisms may vary cyclically or chaotically (rather than being steady, as usually is assumed implicitly). (Edited author abstract) Refs.

## Computation

**083919 PERIODIC STRUCTURE BEYOND A HOPF BIFURCATION.** A Hopf bifurcation where a stable fixed pointer bifurcates into a stable periodic orbit as a parameter passes through a critical value occurs frequently in nonlinear problems. Here, the Maynard Smith nonlinear map in population dynamics involving a parameter  $k$  is analysed with the help of numerical experiments in order to determine the periodic structure of the map beyond the primary Hopf bifurcation of period 6 which occurs at  $k = 1$ . The interesting result obtained is that in the parameter range from  $k = 1$  to the value for blow-up of all initial conditions, there are successive windows of periods 7, 8 and 9, the last containing a secondary Hopf bifurcation of period 4. (Author abstract) 7 refs.

## Mathematical Models

**083920 SURVEY OF CENSUS BUREAU POPULATION PROJECTION METHODS.** Population projections methods of the US Census Bureau draw upon several different traditions of forecasting: demographic accounting, judgmental, time series, deterministic, and explanatory. This paper reviews each of the forecasting traditions in population projections, describe the US Census Bureau's current methods for national and state population projections, and proposes new hybrid approaches such as demographic-time series methods for national fertility projections and economic-demographic methods for state migration projections. Throughout the article, possible parallels with forecasting in other disciplines are noted. (Author abstract) 80 refs.

## Research

**083921 COMPETING RISK THEORY APPROACH TO THE NATURE OF THE OUTCOME OF CONCEPTION.** An attempt has been made to obtain the probabilities of pregnancy termination by live birth, still birth and abortion, in any particular order, assuming that the termination of pregnancy is associated with three competing 'risks', i.e., live birth, still birth and abortion, which need not necessarily operate at the same point of time. A probability model has been constructed to obtain the conditional probability of live birth/still birth/abortion given that the previous pregnancy has been terminated by a particular one of the three. The correlation coefficient between the outcomes of two particular consecutive pregnancy terminations, viz., live birth and reproductive wastage has also been obtained. Given data pertaining to sample correlation coefficients between the nature of consecutive orders of the outcomes of conception from first to sixth, an exercise has been undertaken to estimate parameters relating to the 'hazard' rates of live births, still birth and abortion. (Edited author abstract) 5 refs.

Biswas, Suddhendu (Univ of Delhi, Delhi, India); Kumar Sehgal, Vijay. *Int J Syst Sci* v 18 n 10 Oct 1987 p 1899-1908.

## Sampling

**083922 RESTRICTED SIMPLE RANDOM CLUSTER SAMPLING PLAN.** A new sampling design is proposed which reduces the spread (and thus travel cost) of a simple random sample in large-scale surveys. It provides at least a partial solution to the problem of non-response. At nearly half the travel cost, the proposed design attains efficiency almost equal to that of the simple random sample mean. (Author abstract). 7 Refs.

## Composition Effects

**083924 OPTIMIZATION OF THE COMPOSITION OF PORCELAIN BODIES USING A MICROCOMPUTER.** The procedures for calculating and correcting the composition of the porcelain bodies is based on the methodological recommendations that determine the order of computations with regard to three main criteria: the adsorption index, the rational composition, and the kaolin number. The authors developed and introduced an automatic system for carrying out operative (operational) calculation of the rational compositions of the raw materials and the bodies and for modelling new body composition when changing over from one raw material composition to another. The technological base of the system is an 'Elektronika-60' microcomputer present in the architecture of the 15VUMS-028-025 computer control system (complex) having an external memory in flexible magnetic disks. Programming consists of three separate problems: calculating the rational composition of the raw material, calculating the mineralogical composition of the body, and modelling the body compositions. 3 refs.

## Drying

**083926 INTENSITY OF ENERGY INPUT DURING RADIATION DRYING OF PORCELAIN PRODUCTS IN METALLIC MOLDS.** The application of porous metallic molds (instead of gypsum molds) in the drying and shaping units used in the production of porcelain components by plastic forming makes it possible to intensify the drying process of the components to a significant extent. An analysis of the progress of the high-temperature drying process shows that the gradients

of the potentials of heat transfer and moisture removal virtually appear right from the beginning of drying and tend to increase continuously with time. During the process of drying at 450°C, separation (detachment) of the products from the mold takes place after 40-45 sec depending on the quality of the working surface of the mold and the magnitude of the forming (shaping) stresses. The criteria of crack formation  $K_2$  and  $K_3$  can be found for any given regime. Their values are determined from the normalized thermograms and hygrograms. Figure 3 shows that the critical values of  $K_2$  increase with increasing stringency (intensity) of the thermal regime. Each regime has a specific value of  $K_{2, max}$ . 3 refs.

**083927 AUTOMATIC CONTROL SYSTEM OF THE TECHNOLOGICAL PARAMETERS (ACS TP) OF DRYING AND FIRING PORCELAIN PRODUCTS.** One of the main functions of ACS TP is assembling (gathering) and processing the information entering from the control object (analog signals from the sensing devices of the technological parameters and digital signals regarding the conditions of the equipment). With reference to the drying and firing processes, these are digital (discrete) signals indicating the quality and the quantity of production of a given drying unit (and the first and the second firing units). The data are recorded in the production manual. Two methods are employed for determining the reliability of the signals of the sensing element: by comparing the current value of the signal with its technically possible limiting value or based on the rate of variation of the signal itself. The second method is based on the fact that, as a rule, the technological parameters of the thermal processes vary slowly whereas the breakdown of the sensing elements causes a rapid change in the signal. In ACS TP of firing and drying, there is a provision for feeding the initiating signals into the memory device of the computer. The initiating signals are distinguished from the signals of the common discrete sensing devices by a smaller impulse duration.

**Manufacture** See Also KILNS—Design.

**083928 INVESTIGATIONS CONCERNING THE WORKABILITY AND PROPERTIES OF A HIGH-ALUMINA PORCELAIN BODY.** The properties of porcelains depend both on the body composition and on the conditions of manufacture. This report deals with the effects of various aluminas on the workability and properties of the fired body. The subject of investigation was an industrial-grade hotel porcelain body made of feldspar, kaolin and quartz. The specimens were obtained by casting. In order to avoid falsifying the effects of the alkali contents of the aluminas on the properties of the slips, no deflocculants were used. In German and English. 5 refs.

**083929 KINETICS OF SHERD (BODY) FORMATION DURING SLIP CASTING.** This paper deals with a study of the specific features of the casting process when evacuation is carried out in porous molds made from different materials and the determination of its main technological parameters. In order to reveal the effect of the physical and technological properties of the material of the molds on the process of casting porcelain products in them, we studied various materials (gypsum, phosphogypsum, and porous ceramics) having a wide range of structural characteristics. Such an approach makes it possible to evaluate the effectiveness of evacuation when using different technological flow sheets and materials. Our studies showed that the relative potential of moisture

extraction increases during evacuation with increasing pore diameter. In order to prevent entrance of the solid particles of the casting body into the pores, the average hydraulic diameter of the pores  $D_{av}$  of the material of the mold was maintained at 1.5–2  $\mu\text{m}$ . At a residual pressure of 0.08 MPa, one can expect an increase in the effectiveness of moisture extraction and a corresponding increase in the effectiveness of sinter formation by 30–60%. 2 refs.

**083930 INTENSIFYING THE SECOND FIRING OF FLAT PORCELAIN PRODUCTS.** The authors determined the optimum regimes of saggerless firing of flat porcelain products. The following parameters were considered to be decisive: the firing temperature of the products, the composition of the furnace atmosphere in the firing zone, the duration of holding the products during different stages of firing, the duration of firing the products, the quality of spreading the glaze, and the deformation and the whiteness of the porcelain products. The obtained results (taking the dimensions of the products and their range, the permissible temperature gradients, and the admissible heating rates into account) formed the basis of our method for calculating the length of the zones of the working channel of the thermal units intended for fast firing and establishing the firing cycle. The results of the industrial tests conducted for establishing the optimum fast second-firing regime of flat porcelain products showed that in the fast tunnel furnaces, when loading the products in the cars having shelves, it is possible to manufacture products having high quality and whiteness by maintaining a firing duration of 4–8 h. The proposed solution for intensifying the firing process of porcelain products is recommended for application at porcelain factories.

**083932 ZUR ANWENDUNG DER ZETA-POTENTIAL-MESSUNG BEI FEINKERAMISCHEN SUSPENSIONEN.** [Utilization of Zeta Potential Measurement in Fine Ceramic Suspensions]. The zeta potential is a parameter which shows the ratio of the electric double layer which forms round dispersely distributed solids in watery media. During sedimentation, washed china clay or other raw materials with clay mineral content - or during production and processing of whiteware casting slips - collochemical reactions are practically always involved. Therefore, the zeta potential (ZP) and its variations is connected to nearly all Fine-ceramics problems where reagents are applied. (Edited author abstract) 12 refs. In German.

Schulle, W. (Bergakademie Freiberg, Freiberg, East Ger); Plueschke, R. *Keram Z* v 39 n 8 Aug 1987 p 785-788.

**083933 SYNTHETISCHE ALKALIHALTIGE FLUSSMITTEL.** [Synthetic Alkali-Containing Fluxes]. Alkali feldspars are widely used as auxiliary flux components for producing densely sintering silicate fine ceramic mixtures. Sufficiently suitable feldspars are not available

in all countries in the necessary quantity and quality. Consequently the question of synthesizing suitable auxiliary fluxes directly from domestic raw materials given. The fundamental possibilities for making an alkali-free synthetic auxiliary flux that corresponds in its effects to feldspars are discussed. On the basis of these considerations, synthetic auxiliary fluxes made by thermal synthesis (about 1100 °C) and hydrothermal synthesis (about 200 °C and about 2 MPa) are evaluated in comparison to feldspars. In both ways it is possible to obtain suitable auxiliary fluxes. (Edited author abstract) 61 refs. In German.

## Mechanical Properties

**083934 MECHANICAL PROPERTIES OF ZIRCON-FELDSPAR PORCELAINS.** Replacing quartz with zircon in feldspar porcelains results in significant improvements in mechanical properties. These are dominated by fired porosity, which in turn is determined by both body composition and packing density. The effects of changing the grain size distributions of the raw materials on the mechanical properties of the body are complex and sometimes obscured by the resulting changes in the particle packing of the body. The aim of this study was to evaluate the use of zircon as the filler in porcelain. 27 refs.

## Microstructure

**083935 MICROSTRUCTURE DEVELOPMENT IN A VITRIFIED ANORTHITE PORCELAIN.** Thermal dilatometry, differential thermal analysis, X-ray diffraction, scanning electron microscopy, and energy dispersive spectroscopy revealed the development of phases and the microstructure on firing bodies containing 40 to 50 wt percent wollastonite, 40 to 50 wt percent kaolin, and 10 wt percent nepheline syenite. Vitrified bodies contained a major glassy phase, submicrometer primary and secondary elongated anorthite crystals, and residual wollastonite. Increasing the content of  $\text{Al}_2\text{O}_3$  by increasing the clay content or by adding fine calcined alumina increased the viscosity of the glassy phase and the ratio of anorthite to wollastonite formed on firing. (Author abstract) 28 Refs.

## Moisture Determination

**083936 DETERMINING THE WATER CONDUCTIBILITY OF WHITEWARE BODIES WITH THE AID OF A PARALLEL-PLATE PLASTOMETER.** This report presents a procedure with which relatively simple means suffice to monitor the transport of water through a plastic body. The approach also makes it relatively easy to characterize different bodies and accommodate them to the given technological requirements through the use of suitable additives. In the course of testing several whiteware bodies, we noticed that the body at the center was considerably stiffer than that of the original specimen. We deduced that a mechanical pressure gradient must have caused an appreciable extent of water migration from the center of the plate towards the outer rim. In German and English. 10 refs.

Leusden, C.O. Pels (Georg-Simon-Ohm Fachhochschule, Nuremberg, West Ger). *CFI Ceram Forum Int Ber DKG* v 64 n 10 Oct 1987 p 383-389.

## Optical Properties

**083937 PORCELAIN WITH IMPROVED WHITENESS.** It is known that the whiteness of porcelain is determined by the quantity of diffuse scattered light. Taking the physical essence of the phenomenon into

account, we postulated that there is a possibility of improving its whiteness by increasing the mullite content in the phase composition of porcelain and by increasing the amount of diffuse scattered light during reflection by introducing the additives possessing a high refractive index. In this case, the difference in the refractive indices of the glassy phase of porcelain and the introduced additive must facilitate an increase in the diffuse scattering of light and, consequently, an improved degree of whiteness. The additives meeting the specifications include zinc oxide (refractive index  $n=2.004$ ). The measurements of density, water absorption, and the ultimate static bend strength make it possible to conclude that addition of 0.05–1% zinc oxide into the composition of the porcelain bodies is accompanied by lowering of the sintering temperature of the porcelain materials by 50–70°C. When 2–5% zinc oxide additive is introduced into the body, the firing temperature decreases by 30–50°C. 3 refs.

Production See Also FILTERS—Design.

**083938 OPERATION PLAN OPTIMIZATION OF PORCELAIN PRODUCTION.** The operation planning process of dining porcelain production is very complicated in respect to computation. It results from differentiated shares of single articles in assumed quality grades and from differing demand structures. The central part of this process, which is described in terms of a linear programming problem with a block structure of restrictions, is discussed in this paper. The solution algorithm based on Benders decomposition idea is presented. Application of Benders decomposition enables programming of the problem for microcomputer equipment. (Author abstract) 4 refs.

## Spectroscopic Analysis

**083939 CONSTANCY IN ELEMENTAL COMPOSITION OF IDENTICAL AND SYMMETRICAL CERAMIC PAIRS.** Porcelains made in Jingdezhen, China, during the Qing dynasty (1644–1911) and the Republic period (1912–1939) have, in the rubidiumstrontium-zirconium-niobium K-lines region, a characteristic feature which is quite different in porcelains made elsewhere (whether in or outside China) and therefore could be a means of detecting modern fake reproductions. The aim of this investigation is to quantitatively study trace elements in this characteristic region in identical and symmetrical ceramic pairs from Jingdezhen. The author presents the results for the 10 ceramic pairs studied. The statistical errors at  $2\sigma$  are roughly 2% for Rb, 3% for Sr, 4% for Zr, and 8% for Y and Nb for samples exposed for 11,000 s. For all elements (Rb, Sr, Y, Zr, and Nb), the values for each pair are either identical or very close. This is particularly the case for Y, Zr, and Nb. However, ceramic pairs of different periods have distinguishing differences in their elemental compositions. 12 refs.

**083942 PROPERTIES OF POROUS NET MATERIALS.** Porous net materials (PNM) are promising for the production of structural members of high temperature systems with transpiration (porous) cooling. The hydraulic resistance of the PNM in the direction parallel to the plane of the nets is 1.3-1.6 times higher than in the perpendicular direction. The values of the coefficients of hydraulic resistance of PNM are lower than in the materials made of the particles of irregular form and similar to the values typical of the materials made of spherical particles. The strength characteristics, hydraulic resistance, heat conductivity, and the uniformity of permeability of the PNMs examined satisfy the requirements imposed on structural members. 7 refs.

**083943 ON BALANCE LAWS FOR FLUID-SATURATED POROUS MEDIA.** The space-averaging formalism of Anderson and Jackson is employed to develop a set of balance laws for a multicomponent mixture. The interactions between the mixture components appear as surface integrals in the averaged (or macroscopic) balance laws. These balance laws are used to study the motion of a porous solid; it is shown that the formulations of Herrmann and Morland are only approximate in that both of these authors neglected the effects of microinertia. The motion of an incompressible Newtonian fluid through a rigid porous matrix is considered, and the assumptions required to recover Darcy's law are discussed. Finally the averaged balance laws are used to derive a first order theory for the motion of fluid-saturated porous media; it is shown that reasonable approximations lead to the balance laws previously derived by Garg, et al. on heuristic grounds. (Author abstract) 16 refs.

**083944 POROUS STRUCTURE OF SOLIDS AND GAS PHASE PRECIPITATION REACTIONS.** Natural and synthetic dispersed and porous materials possess individual characteristics of structure, depending on the form and structure of the primary particles and the methods of combining them or distributing the components in the original solid body and if the porous material is obtained by destructive methods. One of the main characteristics of the porous structure is the magnitude and distribution of the pore sizes. The elements of porosity in the structure can be classified according to the regimen of gas transfer into the pores. The proposed double classification divides all known types of systems into groups. 21 refs.

**083946 POPIS VLNUTI POREZNICH MATERIALU JAKO ULOHA STEFANOVA TYPU.** [Description of Moisture Transport in Porous Materials as a Problem of the Stefan Type.] A model is derived for simulation of transport of humidity in porous materials regarding simultaneously the diffusion and convection. An analysis is performed of some input parameters of proposed model. The purpose of the analysis is determination of the velocity of convection  $v$  as well as of the coefficient of humidity and their transportability  $\chi_m$ . For convective velocity is assumed linear dependency on the location. Regarding the theory of mixtures and Vodak's model of area of discontinuity in continuum there have been derived the magnitudes of such velocity in node  $x=0$ . (Edited author abstract). 17 Refs. In Czech.

## Adsorption

**083947 ADSORPTION FROM SOLUTION OF NONELECTROLYTES BY MICROPOROUS CRYSTALLINE SOLIDS: ETHANOL-WATER/SILICALITE SYSTEM.** A simple technique is developed which, for the first time, has enabled the experimental determination of the amount and composition of substances adsorbed from solution by microporous solids. The experimental results determined for the system [ethanol(1)-water(2)]/silicalite show considerable discrepancies with the predictions based on the available theories of adsorption from solution. The experimental determination of the (individual) adsorption isotherms enables, for the first time, the calculation of the activity coefficients and the molar excess Gibbs free energy of the adsorbed phase independent of any a priori assumption other than the existence of a distinct adsorbed phase. For the system [ethanol(1)-water(2)]/silicalite, the activity coefficients show considerable negative deviations from ideality and the molar excess Gibbs free energy is a strong function of spreading pressure as well as composition of the adsorbed phase. (Edited author abstract). 30 Refs.

**Analysis** See Also FILTERS—Porosity.

**083948 MICROGEOMETRY OF RANDOM COMPOSITES AND POROUS MEDIA.** For practical applications of variational bounds to the effective properties composite materials, the information available is often not that required by the formulae for the optimal bounds. The strategy employed in this paper differs from these earlier approaches in that the key quantities that we analyze are the parameters of the microgeometry. Our purpose is to derive some of the the microgeometry. Our purpose is to derive some of the more important relationships that exist among the geometrical parameters and the material properties. Some new bounds are presented on bulk modulus, shear modulus and electrical conductivity that improve on the Hashin-Shtrikman bounds when a measurement of another physical property has been made. For porous materials, these bounds have particularly simple analytical forms. Such cross-property bounds may prove to be quite useful when one material property is easy to

measure but the other is not. The present results are restricted to isotropic two-phase materials such as porous media with easily distinguished solid and void phases. (Edited author abstract) 29 refs.

## Combustion

**083949 INITIATION OF LOW-TEMPERATURE FILTRATION COMBUSTION WAVES FOR POROUS SYSTEMS.** In this work a numerical modeling method was used to study: local ignition in the central part of a porous specimen of 'infinite' (from the point of view of its excluding the effect of boundary conditions) length; initiation of a counter FC (Filtration Combustion) wave by local warm-up of the rear (in relation to the direction of gas filtration) part of the specimen; formation of an associated inverse FC wave warm-up of its frontal part. The aim of this study is to clarify the features of FC wave dynamics, the effect on it of temperature  $\Theta_p$  and width of the firing zone (warm-up)  $L_p$ ; to establish the relationship between the minimum (critical) ignition temperature  $\Theta_i$  and  $L_p$  with different regime parameters and characteristics of the physical system; to determine the ignition time  $\tau_i$  and the amount of 'flashback' of the oxidant during firing. The authors indicate possibilities for optimizing FC wave formation in technological applications. Consideration of the dependence of the energy contribution from an external source, necessary for ignition, on size of the warm-up zone, and also the dependence of integral flashback of the oxidant on the same parameter, makes it possible to draw conclusions about the economic, and in the case of a toxic oxidant, the ecological preference, for warm-up of narrow zones of material. 12 refs.

## Creep

**083951 DAMAGE EVOLUTION AND RUPTURE IN CREEPING OF POROUS MATERIALS.** The configurational evolution in time and space of two-dimensional ellipsoidal damage into an elongated flaw with preferred orientation is solved and studied. The damage is represented as a single, traction free, ellipsoidal void embedded in an infinitely large time-dependent porous-like solid. The solid creeps in a power-law fashion under static biaxial loads which induce a large-scale rotation (with volume enlargement/contraction) of the void. In the special case of unidirectional loading the free boundary of the void evolves into an expanded and elongated new shape while rotating towards a position codirectional with the principal tensile axis. The process simulation agrees well with visual observations of void expansion and rotation in a highly viscous material and with experimental measurements of the rupture ductilities of creeping materials with different strain-rate sensitivity index. Similarities and dissimilarities with existing phenomenological damage theories are discussed. (Edited author abstract). 15 Refs.

## Deformation

**083952 PLASTIC DEFORMATION OF POROUS SOLIDS AT LOW POROSITY.** Plastic deformation of a porous solid under a compressive load (at a negative isostatic component of the stress tensor) brings about a decrease in its porosity, i.e., pore healing. On the other hand, plastic deformation of the matrix of a porous solid loosens its structure, i.e., results in the formation of new pores. When a solid is close to being nonporous, the two processes begin to compete with each other. In the present work, a model of a porous solid is proposed allowing for this effect, and conditions are determined under which a state of equilibrium is attained. 7 refs.

Beigel'zimer, Ya.E. (Acad of Sciences of the Ukrainian SSR, USSR). *Sov Powder Metall Met Ceram* v 26 n 3 Mar 1987 p 193-195.

**083953 PLASTIC DEFORMATION EQUATIONS FOR A STRENGTHENING MEDIUM WITH A POROUS STRUCTURE.** It has been postulated that a porous material is characterized by an ellipsoidal plasticity surface. Today preference tends to be given to a model allowing for the strengthening of the matrix of a porous medium which takes place as a result of a widening of its plasticity surface. Now with the assumption that strengthening is merely a process of isotropic widening of a flow boundary it is not possible to describe the deformation anisotropy of a plastic material. However, the strengthening process of a material may be treated in the same way as the process of displacement of its starting flow surface, and we are then dealing with translational strengthening. That such displacement does not occur is indicated by the fact that the majority of metals exhibit a Bauschinger effect. The present work was therefore undertaken with the aim of deriving determining equations of plastic deformation for a porous material whose solid phase behaves in accordance with the relationships of the theory of translational strengthening. 11 refs.

## Dielectric Properties See SILICA—Thick Films.

## Diffusion

**083955 PRESSURE CHANGES DURING DIFFUSION WITH CHEMICAL REACTION IN A POROUS PELLET.** A method is proposed for evaluation of the pressure change in an isothermal porous pellet within which a single chemical reaction takes place, accompanied by mass transfer by Knudsen diffusion, bulk diffusion and viscous convective flow of the reacting mixture. The dimensionless pressure is expressed as a function of two dimensionless parameters which characterize transport mechanism and mixture properties respectively. The pressure change also depends on the reaction and on the mixture composition on the pellet surface. The method requires numerical integration of an initial-value problem. A simple analytical method is also proposed for estimation of the maximum possible pressure changes in the system, both for the Knudsen diffusion control regime and for the bulk diffusion with viscous convective flow control regime. Both methods are illustrated by the computed results for a general two-molecule reaction and for the ammonia synthesis reaction. (Author abstract) 15 refs.

**083957 ANALYSIS OF MULTICOMPONENT DIFFUSION IN PORE NETWORKS.** Diffusion flux models are developed for isobaric diffusion of a multicomponent gas mixture in pore networks of distributed pore size and length constructed by arranging pore segments around the bonds of a lattice of constant coordination number. Eigenvalue-eigenvector analysis is used to decompose the dusty-gas model equations, written for each pore segment in the network, into a set of independent single-species diffusion problems, each of which is then treated by combining the effective medium theory for resistor networks with the smooth field approximation. Results for a ternary mixture diffusing in a porous slab show that direct application of the smooth field approximation underestimates significantly the mass transport resistance. (Edited author abstract). 24 Refs.

**083958 COMPLETE MODEL OF THE DRYING CURVE FOR POROUS BODIES - EXPERIMENTAL AND THEORETICAL STUDIES.** Non-hygroscopic, capillary porous bodies, saturated with liquids were dried in an experimental device. By systematically varying the drying agent, the liquids and the differently structured samples, a wide range of drying rate curves were found experimentally and evaluated. The basic equation for the model of the constant-rate drying period refers - according to Krischer - to capillary liquid transportation only. The liquid-diffusion coefficient dependent on moisture content is calculated on the basis of the model considerations of Rumpf. For the falling-rate period the well-known receding drying front model is modified with regard to the capillary liquid movement. (Author abstract) 15 refs.

**Elasticity** See Also MECHANICAL WAVES.

**083959 DEPENDENCE OF ELASTIC CONSTANTS OF AN ANISOTROPIC POROUS MATERIAL UPON POROSITY AND FABRIC.** The elastic properties of an anisotropic porous material can be represented as functions of the material's solid volume fraction (or porosity) and the principal diameters of the material's fabric ellipsoid. The fabric ellipsoid is a measure of the anisotropy of the microstructure of a material. The definitions and measurement techniques for fabric ellipsoids in granular materials, foams, cancellous bone, and rocks are discussed. The principal results presented in this work are algebraic expressions for the dependence of the

orthotropic elastic constants upon both solid volume fraction and the fabric ellipsoid. (Author abstract) 25 refs.

## Electric Conductivity

**083960 SCALING LAW FOR THE LOW-FREQUENCY A.C. CONDUCTIVITY OF FLUID-SATURATED POROUS MEDIA.** An empirical scaling law for the real part of the frequency-dependent electrical conductivity  $\sigma'(\omega)$  of brine-saturated porous materials in relation to its d.c. limit has been identified. This scaling law relates the conductivity as a function of frequency, porosity and salinity to a function of only one variable that is the ratio of the frequency to the d.c. conductivity in appropriate units. This result is very similar to what has been reported in hopping semiconducting systems. (Author abstract) 3 refs.

## Explosions

**083961 NATURE OF FAILURE AND FILTRATION PROPERTIES FOR A POROUS GAS-IMPREGNATED MATERIAL FOLLOWING CAMOUFLET EXPLOSION.** In the case of carrying out a camouflet explosion in a porous gas-impregnated material the nature of change in filtration properties depends markedly on the initial material porosity. With the aim of studying the dependence of the change in permeability caused by a camouflet explosion on the initial material porosity, laboratory experiments have been carried out with artificially prepared models of a porous collector having different porosity values. Results of experiments point to the presence of a qualitative difference in permeability factor after an explosion in materials with porosities  $m_0 > 15$  and  $< 15\%$ . A circulation model is suggested explaining this effect by change in structure of the pore space. Specific mechanisms leading to occurrence of this effect may be varied: crushing of grains, failure of intergranular cement, etc. 7 refs.

## Failure

**083962 EFFECT OF POROSITY DISTRIBUTION ON DUCTILE FAILURE.** The effect of a nonuniform distribution of porosity on flow localization and failure in a porous material is analyzed numerically. The void density distribution and properties used to characterize the material behavior were obtained from measurements on partially consolidated and sintered iron powder. The calculations were carried out using an elastic viscoplastic constitutive relation for porous plastic solids. Local material failure is incorporated into the model through the dependence of the flow potential on void volume fraction. The results suggest a failure criterion based on a critical void volume fraction that is only weakly dependent on stress history. The critical void fraction does, however, depend on the initial void distribution and material hardening characteristics. (Author abstract) 30 refs.

## Freezing

**083963 EFFECT OF MAXIMUM DENSITY OF WATER ON FREEZING OF A WATER-SATURATED HORIZONTAL POROUS LAYER.** This experiment simulates the freezing of water in a layer of earth by the use of a porous bead layer. The layer is cooled from above. The beads are 1, 5, and 11-mm-dia glass and

11-mm-dia steel. When the predominant heat transfer mode in an unfrozen layer is conduction, the freezing rate is not affected by the bead diameter. However, in natural convection the freezing rate is greatly affected by the maximum density of water at 4°C. An approximate numerical analysis which does not treat the maximum density effects predicts well the freezing rate in the range of  $0^\circ\text{C} < T_2 < 4^\circ\text{C}$  and  $26^\circ\text{C} < T_2$  ( $T_2$  = the lower plate temperature). (Author abstract) 14 refs.

**083964 THERMAL CONVECTION IN A POROUS LAYER: EFFECTS OF ANISOTROPY AND SURFACE BOUNDARY CONDITIONS.** The theory describing the onset of convection in a homogeneous porous layer bounded above and below by isothermal surfaces is extended to consider an upper boundary which is partly permeable. Estimates of the magnitude and horizontal distribution of the vertical mass and heat fluxes at the surface, the horizontally-averaged heat flux (Nusselt number) and the fraction of the fluid which recirculates within the layer are found for slightly supercritical conditions. (Edited author abstract) 15 refs.

McKibbin, Robert (Univ of Auckland, Auckland, NZ). *Transp Porous Media* v 1 n 33 1986 p 271-292.

**083965 HEAT TRANSFER IN AN UNEVENLY HEATED POROUS LAYER.** For a uniform saturated porous layer heated from below, the dependence of the quantity of heat transferred on the distribution of the heat source is investigated. It is found, using perturbation methods and numerical techniques, that very small nonuniformities in the heat source having the same wavelength as the preferred convection mode significantly reinforce natural convection. (Author abstract) 19 refs.

O'Sullivan, M.J. (Univ of Auckland, Auckland, NZ); McKibbin, R. *Transp Porous Media* v 1 n 33 1986 p 293-312.

**083966 EFFECTIVE EQUATION GOVERNING CONVECTIVE TRANSPORT IN POROUS MEDIA.** The fine structure of disordered porous media (e.g., fully saturated randomly packed beds) causes microscopic velocity fluctuations. The effect of the spatial and temporal randomness of the interstitial velocity field on the convective transport of a scalar (heat or mass) is investigated analytically. For a uniform mean velocity profile, the effective heat transport equation is obtained as the equation governing the transport of the ensemble average of the scalar under conditions of steady or unsteady random fields (with given statistics). In both cases, it is shown that the effective transport coefficient is enhanced by a hydrodynamic dispersive component, which is an explicit function of the mean filtration velocity. The agreement with experiments is encouraging. (Edited author abstract). 18 Refs.

Georgiadis, J.G. (Univ of California, Los Angeles, CA, USA); Catton, I. *J Heat Transfer Trans ASME* v 110 n 3 Aug 1988 p 635-641.

**083967 THERMAL CONVECTION AROUND A HEAT SOURCE EMBEDDED IN A BOX CONTAINING A SATURATED POROUS MEDIUM.** A study of the thermal convection around a uniform flux cylinder embedded in a box containing a saturated porous medium is carried out experimentally and theoretically. The experimental work includes heat transfer and temperature field measurements. It is observed that for low Rayleigh numbers, the flow is two dimensional and time independent. Once a critical Rayleigh number is exceeded, the flow undergoes a Hopf bifurcation and becomes three dimensional and time dependent. The theoretical study

involves the numerical solution of the two-dimensional Darcy-Oberbeck-Boussinesq equations. The complicated geometry is conveniently handled by mapping the physical domain onto a rectangle via the use of boundary-fitted coordinates. The numerical code can easily be extended to handle diverse geometric configurations. (Edited author abstract). 17 Refs.

## Manufacture

**083968 POROUS MATERIALS PREPARED BY HEATING DERIVATIVES FROM HALLOYSITE.** Halloysite clay was subjected to treatment by trimethylsilylation and hydrochloric acid. The resulting derivatives were heated below 1473 K in nitrogen or air to prepare thermally stable porous materials including larger pores than in zeolite. The trimethylsilylated halloysite resulted in a thermally stable porous material, in an amorphous state, including extremely uniform pores of 1.7 nm. Another derivative also resulted in a thermally stable porous material but consisted of very heterogeneous pores. The thermal degradation behavior of both derivatives is discussed in detail. (Author abstract) 5 refs.

**083970 AXISYMMETRIC FUNDAMENTAL SOLUTIONS FOR A COMPLETELY SATURATED POROUS ELASTIC SOLID.** This paper is concerned with the derivation of axisymmetric fundamental solutions that are required in the application of boundary integral equation method to solve complicated boundary-value problems involving poroelastic semi-infinite and infinite domains. General solutions for fully saturated poroelastic solid derived through the application of Laplace and Hankel integral transforms with respect to time and radial coordinates are utilized in the analysis. The derivation of complete fundamental solutions requires the consideration of three boundary-value problems involving unit buried ring loads acting in the vertical and radial directions and a unit buried ring flow source. These boundary-value problems are solved for both half space and full space regions. Explicit solutions for Laplace transform of displacements, tractions, pore fluid pressure and fluid flow are presented. (Edited author abstract) 30 refs.

**Measurements** See Also ZEOLITES—Measurements.

**083971 NMR TECHNIQUE FOR THE ANALYSIS OF PORE STRUCTURE: DETERMINATION OF CONTINUOUS PORE SIZE DISTRIBUTIONS.** NMR measurements of the spin-lattice relaxation decay time for a fluid in a porous solid have been previously

demonstrated as a significant tool for pore size/structure analysis. The analysis requires the solution of a Fredholm integral equation of the first kind to extract the desired  $T_1$ , and therefore, pore size distribution from the relaxation measurements. In this work, the method of regularization is applied to extracting continuous pore volume distributions from relaxation measurements. The validity of the approach used to calculate the optimum value of the regularization smoothing parameter given an expected noise level and the data are demonstrated using 'data sets' generated from known 1 distributions. Varying levels of random noise are added to these data sets and the  $T_1$  distribution is calculated for comparison to the starting distribution. For error levels in the range of 0.001 to 0.01, agreement between the starting and the calculated distributions is good. (Edited author abstract) 11 refs.

**Mechanical Properties** See Also MATERIALS TESTING APPARATUS—Retrofitting; SOLIDS—Mechanical Properties.

**083972 EVALUATING THE RIGIDITY AND TENSILE STRENGTH OF HIGHLY POROUS FIBROUS MATERIALS.** A model is suggested for calculating the mechanical characteristics of sintered highly porous fibrous materials (HFM) (porosity 90%) in which the measured characteristics of the microstructure of the material are used as initial parameters: mean length and diameter of fibers, anisotropy of fiber arrangement, size of contact bridge, also mean mechanical characteristics of the fibers. It was assumed that fibers arranged along the direction of expansion has a finite length and are loaded by the bending of transverse fibers in contact with them which fulfill the role of a matrix (transfer of shear stresses). The concept is introduced of a value for the contact bridge (CB) between the fibers of the HFM. (Edited author abstract) 11 refs.

Toropov, A.I.; Nepershin, R.I. *Sov Mach Sci* n 2 1987 p 47-53.

**083973 MECHANICAL AND FRACTURE BEHAVIOUR OF POROUS MATERIALS.** The elastic moduli of porous materials represented as a combination of spherical, cylindrical or disk shaped holes or solid elements was calculated using a self consistent method. A yield criterion could be found by stating that the elastic distortion energy evaluated with these moduli was equal to a critical value. Another yield criterion could be approximated from the results of finite elements computations using the homogenization technique. These criteria possess the same homogeneity as the yield criterion of the dense material. The fracture toughness of syntactic foams could be explained by the local stress distribution in the glass spheres. In the case of ductile porous nickel the COD at initiation decreased as the fracture strain. This material exhibited a large tearing modulus whose decrease when the porosity was increased could be taken into account by the damage parameter. Fatigue crack propagation rates could also be rationalized with the use of the damage parameter and by reducing the surface of the material to be fractured. (Edited author abstract) 34 refs.

Bompard, Ph. (Ecole Centrale des Arts et Manufactures, Châtenay Malabry, Fr); Wei, Dan; Guennou, T.; Francois, D. *Eng Fract Mech* v 28 n 5-6 1987 p 627-642.

**083974 STATISTICAL ANALYSIS OF STRENGTH OF POROUS FIBROUS MATERIALS WITH NONUNIFORM STRUCTURE.** A statistical model is constructed for strength during elongation of highly porous fibrous materials containing regularly alternating region of high (grain) and low (lamella) density. The strength of the elementary structural cell, consisting of the grain and lamella, is modeled by a Weibull distribution with parameters determined from the experimental distribution of density of the lamella. The model of strength of a sample of finite dimensions was obtained according to the

statistical theory of independent parallel loaded elements in a layer of material and according to the hypothesis of a weak link for consecutively loaded layers. Using a specific material as example, the statistical strength parameters are determined. (Edited author abstract) 8 refs.

**Microstructure** See Also FLOW OF FLUIDS—Porous Materials.

**083975 INFLUENCE OF PROCESSING ON THE MICROSTRUCTURE OF MATERIALS.** The topic described by this title is an extremely broad one. However, it will be limited mainly to the consideration of porous materials, and in particular to such materials that have a constructional engineering function. Whereas some porous materials employed in construction (or in the decoration of structures) are used in their more-or-less natural state (e.g. soil, timber, stone, natural pigments), others (such as cement, concrete, plaster, ceramics, plastics and paint) are processed during manufacture, and may even be contrived wholly artificially. Relationship between pore structure and properties, and the influence of processing on pore structure - are in fact two of the principal questions addressed at the Versailles Congress 'From materials science to construction materials engineering'.

#### Moisture Determination

**083976 EXPERIMENTAL DETERMINATION OF MOISTURE CHARACTERISTICS OF PERLITE AGGREGATES AND VERIFICATION OF THE VALIDITY OF THE COMPUTED K-H (OR K-0) RELATIONSHIPS THROUGH THE COMPARISON OF EXPERIMENTAL AND SIMULATED INFILTRATION.** The purpose of this paper is to investigate the validity of computational models in estimating the unsaturated hydraulic conductivity of a porous material, based on the knowledge of the experimentally obtained moisture characteristic curve and the value of the hydraulic conductivity at saturation,  $K_{\text{sat}}$ , by means of comparing the experimental and simulated process of infiltration. The comparison of the experimental cumulative infiltration versus time curve with that obtained by solving the appropriate Richard's equation numerically, under the same initial and boundary conditions shows that the computed K- $\theta$  (or K-H) relationships, where K is the hydraulic conductivity of the porous material and  $\theta$  the volumetric water content, H the matric potential, can give reliable information about the unsaturated hydraulic conductivity and can be used in water movement simulation studies. We investigate perlite, a porous material which recently gains grounds as a soil additive, as a greenhouse potting compost or as a substrate for hydrocultures. (Edited author abstract). 32 Refs.

**083977 PERMEABILITY OF A RANDOM ARRAY OF FRACTURES OF WIDELY VARYING APERTURES.** The authors modelize a fractured rock by a random array of plane cracks of finite extent having a very broad distribution of apertures (or of hydraulic conductances). If the rock is permeable, the flow will essentially take place along a 'subnetwork' made of the less resistant cracks. Using an analogy with the treatment of variable range transport in semiconductors, the authors evaluate the homogenization length and the permeability of this disordered network. This evaluation makes use of the

notion of the critical bonds which are the weakest cracks among the good ones necessary for percolation; the remaining weaker bonds make a negligible contribution to the permeability. The method is applicable to other examples of transport in very heterogeneous macroscopic random materials. (Edited author abstract) Refs.

**083978 ACOUSTIC METHOD OF DETERMINING HYDRAULIC RESISTANCE FOR A POROUS BODY.** Determining the pneumatic and hydraulic resistances, or the permeability, of porous bodies is a common technological problem. It is solved, as a rule, by applying to the specimen being tested a pressure differential that is constant or is varying in accord with a specified law and measuring by some means the volumetric rate of flow. Drawbacks of existing methods are pointed out and modifications are suggested. 9 refs.

Mamin, V.M. *Meas Tech* v 30 n 4 Apr 1987 p 364-368.

**083979 EFFECTS OF VOIDS AND VOLUME CHANGES ON THE BEHAVIOR OF FRICTIONAL MATERIALS.** Development of constitutive models for engineering materials is often based on a framework of elasticity and plasticity theories as developed for metals. Presented here is a review of some of the basic differences in the experimentally observed behavior of metals and frictional materials. Two of the distinguishing characteristics between metals and frictional materials are the absence or presence of voids and the tendency to change or maintain constant volume during compression and shear. These differences must be recognized in order to develop reasonable constitutive models for frictional materials. (Author abstract). 22 Refs.

Lade, Poul V. (Univ of California, Los Angeles, CA, USA). *Int J Numer Anal Methods Geomech* v 12 n 4 Jul-Aug 1988 p 351-370.

#### Plasticity

**083980 INFLUENCE OF THE PORE MORPHOLOGY AND SECONDARY CAVITIES ON THE PLASTIC BEHAVIOR OF POROUS MATERIALS.** Using homogenization technique, the plastic behavior of a porous material containing two populations of cavities is constructed. The corresponding load function is given. It is shown that the interaction between the main and the secondary cavities greatly increases the relative growth rate of the porosity. This effect is more important the higher the stress triaxiality ratio or the smaller the ratio between the main and the secondary porosities. The influence of the pore morphology on the yield criterion of porous material is also studied. It is shown that the pore morphology modifies the yield criterion only for high triaxiality ratio. For small or medium ones, the main effect comes from the porosity. (Author abstract). 12 Refs.

**Porosity** See Also FLOW OF FLUIDS—Porous Materials.

**083981 TRANSIENT METHOD FOR MEASUREMENT OF EFFECTIVE POROSITY.** This paper describes a new and simple method for determination of effective porosity with transient flow of gases through a porous media. The unsteady flow of gases through porous media is influenced by effective porosity. Authors have expanded numerical model and method used by Aro-nofsky and Jenkins by including the time for inlet pressure to rise in order to construct the method of measuring effective porosity of a porous media. On the basis of the numerical calculation, the timelag, required for gas flowing out to the half steady state from the time of the inlet pressure to rise to the half, was related to the characteris-

tics of gas flow such as effective porosity, permeability and so on. Present method was successfully applied to measure the three samples of porous media formed by compressing powder aluminum and powdered coal. By flowing gases uniformly through each sample, permeability, Klinsenberg's constant, effective pore-area and mean pore-radius were measured. And each effective porosity and tortuosity were determined on the measured timelag of the transient outlet flow which was generated by giving impetuous inlet pressure. (Author abstract) 14 refs. **083982 CALCULATION OF CONTINUOUS PORE SIZE DISTRIBUTIONS FROM ADSORPTION ISOTHERMS.** The analysis of gas/vapor condensation and evaporation in a porous solid is widely applied for the determination of pore size distribution (PSD). By assuming a pore shape, the relative pressure corresponding to phase change and size are related via the Kelvin equation. However, the Kelvin radius is less than the actual pore size as a result of the presence of an adsorbed film on the pore wall. Thus, in order to extract a PSD from an adsorption/desorption isotherm, one must account for both sorption and phase change. The authors demonstrate that with the use of a more sophisticated computation scheme, additional pore structure information may be extracted from condensation/adsorption data on monodisperse silica spheres produced by sedimentation and a silica xerogel produced via the hydrolysis of tetraethyl orthosilicate. 9 Refs.

#### Production

**083983 POROUS SILICATE BEADS BY GELATION.** The sol-gel preparation of porous spherical beads in the system  $\text{SiO}_2\text{-ZrO}_2\text{-TiO}_2\text{-Al}_2\text{O}_3$  is described. A uniformly reacted single precursor is dispersed in an aqueous phase and the as-formed droplets are gelled by the addition of  $\text{NH}_4\text{OH}$ . After drying, the spheres are subsequently oxidized and partially densified by heat treatments in air. Physico-chemical data indicate that these materials are glassy up to about 650°C and are more resistant to chemical attack than pure silica samples. (Author abstract) 10 refs.

#### Radiation Effects

**083984 MOMENTUM REDISTRIBUTION IN A BRIEFLY, INTENSELY IRRADIATED, STRUCTURAL ELEMENT.** An unsteady one-dimensional treatment is undertaken of the response of a semi-infinite porous medium (modeled as a viscoelastic material) to a very intense, brief burst of radiation. Of special interest is the redistribution of the momentum of the impulse by a stress wave, so that the momentum is shared over an appreciable thickness of the medium. A similarity solution is found to describe the Lagrangian-position displacement of the material particles for a broad class of uniform media described by a generic, nonlinear stress/rate-of-strain relation. For a specific stress/strain rate relation sensitive primarily to the porosity of the medium, numerical results are obtained to the pertinent two-point boundary-value problem. In particular, the increase in the maximum (i.e., surface particle) displacement and in the breadth of the momentum distribution is found for given magnitude of the impulse. (Edited author abstract) 1 ref.

### Spectroscopic Analysis

**083985 NMR TECHNIQUE FOR THE ANALYSIS OF PORE STRUCTURE: APPLICATION TO MESOPORES AND MICROPORES.** In this work, we explore the extension of NMR technique to porous solids with pores in the micropore and mesopore size ranges. By comparing previously published results of the relative distribution of surface- and bulk-phase water as a function of pore size to predictions from various pore models, we have demonstrated that the 'two-fraction, fast exchange' model may be applied to relate measured  $T_1$  to pore size in the mesopore and micropore size range if the pore geometry is known (or assumed). For pore size greater than 5 nm, pore geometry is not important. Comparisons between conventional techniques, such as nitrogen sorption and mercury porosimetry, and the results of NMR spin-lattice relaxation experiments are complicated by the fact that different pore structure parameters are measured with these methods. Despite this, agreement between the methods is quite good for the five sol-gel-derived materials which we have studied. (Edited author abstract) 14 Refs.

Stresses See Also COAL MINES AND MINING—Hydraulic Process.

**083986 COUPLED PROBLEMS ON THE STRESSED STATE OF SATURATED POROUS MEDIA IN THE VICINITY OF NONCIRCULAR CYLINDRICAL CAVITIES.** There are a number of problems in the mechanics of saturated porous media in which the change in the stress-strain state of the medium created by filtration of liquid or gas is accounted for. Using an approximate formulation of the problem, which can often yield satisfactory results, the inverse effect of strain of a saturated medium on the filtration process is typically neglected. In this study, a method is formulated for solving the coupled problems of the stressed state of a saturated porous medium in the vicinity of noncircular cylindrical underground mine. This approach is based on the combined application of the first variant of the boundary perturbation method and the integral Laplace transformation with respect to time. 10 refs.

**083987 THEORY OF NONLINEARLY VISCOUS AND PLASTIC BEHAVIOR OF POROUS MATERIALS.** To determine macroscopic stresses using the concept of rms stresses and deformation rates, it is only necessary to know the rheological properties of the solid phase. The latter may be described by a relationship permitting an ultimate transition to a rigid-plastic model. This method has other advantages linked with the fact that it is based on the employment of principles of the thermodynamics of irreversible processes. These considerations prompted the authors to examine positions lying at the basis of the concept of root mean square parameters and formulate their premises in a general form in order to develop a model of a nonlinearly viscous porous solid enabling creep effects to be allowed for. 7 refs.

**083990 MACROSCOPIC MODELLING OF TRANSPORT PHENOMENA IN POROUS MEDIA. 1: THE CONTINUUM APPROACH.** This paper presents a systematic development of a continuum model of a porous medium and of transport processes occurring in it. The concept of a Representative Elementary Volume (REV) as opposed to any arbitrary volume of averaging quantities at the micro-scale, is quantified. A universal criterion for selecting the size of an REV as a function of measurable characteristics of a porous medium and selected tolerance levels of estimation errors, is developed. The rules of spatial averaging are extended by including the effects of both the configuration of the solid matrix and of interphase transfer phenomena within an REV. (Edited author abstract) 18 refs.

**083991 MACROSCOPIC MODELLING OF TRANSPORT PHENOMENA IN POROUS MEDIA. 2: APPLICATIONS TO MASS, MOMENTUM AND ENERGY TRANSPORT.** In this paper, the averaging rules are employed in order to develop a general macroscopic balance equation and particular equations for mass, mass of a component, momentum and energy, all of a phase in a porous medium domain. These balance equations involve averaged fluxes. Then macroscopic equations are developed for advective, dispersive and diffusive fluxes, all in terms of averaged state variables of the system. These are combined with the macroscopic balance equations to yield field equations that serve as the core of the mathematical models that describe the transport of extensive quantities in a porous medium domain. (Edited author abstract) 10 refs.

Bear, Jacob (Technion-Israel Inst of Technology, Haifa, Isr); Bachmat, Yehuda. *Trans Porous Media* v 1 n 33 1986 p 241-269.

**083992 CLOSED TUBE METHOD FOR MEASURING GAS DIFFUSION COEFFICIENTS.** A transient, closed tube method for measuring both ordinary gas diffusivities and porous media effective diffusivities is

presented. The current method is suitable for measuring gas diffusivities in air-dry systems over a range of temperatures. Gas concentrations are continuously monitored in a well-stirred volume of a single end chamber, which is connected to a closed sample chamber during experiments. An analytic solution for this diffusion process is available in which, after a sufficient time, the diffusivity of the sample is obtained from the slope of the logarithm of dimensionless concentration excess versus time. The method was checked by comparing measurements of  $N_2-O_2$  gas diffusivities at 0, 30, and 60°C to various previously reported values in the literature. (Edited author abstract) 29 refs.

**083993 SCALE-DEPENDENT EQUATION FOR SOLUTE TRANSPORT IN POROUS MEDIA.** The governing equation describing solute transport in porous media is reformulated using standard volume averaging techniques. The alternative formulation is based on a modified definition of the deviation, which allows for variation of macroscopic velocity across the REV. The new equation contains additional scale-dependent terms which are functions of the size of the averaging volume (REV). This result indicates that the scale-dependent nature of the dispersion phenomenon is inherent even at the scale of the REV. (Author abstract) 12 refs.

### Vaporization

**083994 INTERNAL VAPORIZATION IN POROUS MATERIALS UNDER LASER IRRADIATION.** Under laser irradiation, a porous material may vaporize within its pores as well as at the surface. The effect of this phenomenon is examined for pores with a high degree of connectivity and for a pore tree model. It is shown that in the former case, the internal vaporization of material is bounded by the rate at which vapor can escape from inside the porous substance. This rate is sufficiently large so that significant modification of the internal temperature profile may result. For the pore tree model, the buildup of vapor pressure in the pores suppresses the internal vaporization. An upper bound on the mass flow rate from the pore tree is derived when the back pressure is self-consistently included. For pore trees of interest, this bound is small enough so that significant modification of the internal temperature profile will not result; however, material damage may occur due to the high internal pressures. (Author abstract) 9 refs.

## Bulkheads

**083998 PREDICTION OF LATERAL DISPLACEMENT OF ANCHORED BULKHEADS INDUCED BY SEISMIC LIQUEFACTION.** Numerical analysis was carried out on earthquake-induced displacement of anchored bulkheads. The permanent displacement of several meters experienced in liquefied areas during the Niigata earthquake was large enough to damage the functions of nearby structures. Since the conventional methods of predicting seismically-induced displacement could not deal with thin sheet-pile walls subject to liquefaction, they were modified and improved. The new method analyzes the limit equilibrium of a backfill soil wedge under the action of pseudostatic seismic force, and calculates the critical acceleration of an earthquake which is required for the sliding mechanism to be activated. By following Newmark's sliding block theory, the seismic acceleration in excess of the critical value is integrated twice with time so that permanent displacement may be obtained. Effects of pore water pressure development is taken into account by allowing the variation of critical acceleration with time. (Edited author abstract) 16 refs.

**083999 QUICKLY ERECTED PORT BUILDINGS PROVE LONGTERM INVESTMENT.** To cope with changing trade patterns, a port needs flexibility in its storage buildings. Traditional-built structures have high cost/long wait disadvantages, while units once regarded as 'temporary' accommodation are now accepted as permanent solutions but retain their relocatable superiority. (Edited author abstract)

Anon. *Port Constr Ocean Technol* v 4 n 2 Mar-Apr 1987 p 43-44.

**084000 STEEL SHEET PILES AS PREFABRICATED ELEMENTS IN HARBOUR CONSTRUCTION.** Installation of sheet piling utilizes pre-fabricated components. Its main features combine immediate construction start-up, simple and overseeable equipment placement, low personal requirement, rapid construction progress and relative weather independence. Sheet Pile Structures are economically adaptable to existing conditions. Extensions, changes or strengthening of old structures to accommodate present demands are possible without difficulties and represent typical areas of applications for sheet piling. Examples for such measures are: redriving of sheet piling to deeper penetrations even after decades; reinforcing sheet piling; strengthening of anchoring systems; installation of additional anchor rods; and splicing to existing piling (e.g. in area of ground subsi-

dence). This is valid both for inland harbors and sea ports, and is applicable also for sheet piling as double or treble piling; armor-plated sheet piling; heavy, wave-shaped sections; combined (mixed) sheet pile structures; flat web sheet piling; and dolphins. (Edited author abstract) 11 refs.

## Design

**084002 CONSTRUCTION OF NEW PRODUCTS-BERTH FOR 80,000-DWT VESSELS.** A new products-berth was designed to accommodate vessels up to 80,000 DWT, thus providing cost savings in ocean freight charges. In Chiba Works the design of the new products-berth was an absolute necessity, in order to utilize the cargo handling equipment and techniques more effectively and economically. The berth is a quay-type wharf structure supported on steel pipe piles. A structure 300-m long and 41-m wide was designed, with a dredge depth of -15.5 m. In this project, each work of dredging and pile installation was completed by using measuring systems. For example, it was necessary to monitor potential movement of the existing concrete-caisson sea wall. This project has three innovative technological features: the KST cantilevered pile driving system for marine structures, polyethylene film coated steel pipe piles, and pile driving control using the wave equation. (Author abstract) 3 refs.

## Poland

**084005 PORT STRUCTURES AND EQUIPMENT.** A brief survey is presented of the historic development of port constructions and equipment in Poland, a country for centuries connected with the sea. Special attention has been paid to the port structures and equipment introduced in the period of reconstruction and development of ports in the estuarine area of the Odra river, e.g. those of Szczecin and Swinoujscie. The author tries to demonstrate that, if the port complex Szczecin-Swinoujscie has attained the actual level of development and become one of the most important merchant ports on the Baltic sea, it is only thanks to having been regained and included within the borders of the Polish state. (Edited author abstract) In English and French. 13 refs.

Mazurkiewicz, Boleslaw (Technical Univ of Gdansk, Pol). *Bull Perm Int Assoc Navig Congr* n 60 Jan-Mar 1988 p 34-45.

## Portable

**084006 DEVELOPMENT OF DEPLOYABLE PORTS MAY PROVE VITAL TO U.S. NAVY.** The deployable port represents a radical departure from current port construction techniques. The port facilities are preconstructed on large (100×300 foot) floating barges. The barge modules are connected and anchored to form a port complex. Construction of the modules can be carried out in shipyards without tying up vital port operation areas. Once constructed, the modules can be installed in a matter of three to four weeks to replace or augment existing stateside port facilities. This article discusses how providing a less expensive, highly mobile alternative to permanent port facilities can achieve greater political and operational flexibility.

## Wave Effects

**084008 WATERLINE OSCILLATION AND RIPRAP MOVEMENT.** Eight test runs using a 1:3 glued gravel slope with an impermeable base were conducted in a wave tank to evaluate and calibrate the numerical model developed previously. For each run with the specified incident wave train generated in a burst, measurements were made of the free surface oscillation at the toe of the slope, the waterline oscillation on the slope, the temporal variation of dynamic pressure on the base of the slope, and the displacements of loose gravel units placed on the glued gravel slope. First, the friction factor associated with the rough slope is calibrated within a relatively narrow range using the measured waterline oscillation. Second, the coefficient for the lift force acting on a sliding gravel unit is calibrated in the range 0.18-0.4 by comparing the measured and predicted displacements of loose gravel units on the 1:3 glued gravel slope. (Edited author abstract) 9 refs.

## Belgium

**084009 ZEEBRUGGE LNG TERMINAL.** The Distrigas Zeebrugge project is the largest LNG terminal in Europe and currently second largest in the world. Total storage capacity is 260,000 cu m with a peak send out capability of 7 billion cu m of natural gas per year. Developed at a cost of £90 million, the terminal will also be the receiving point for Statoil's Zeepipe. This will transport Norwegian gas from Troll and Sleipner and place Zeebrugge for the future expansion of European gas distribution.

Anon. *Pet Times* v 91 n 2216 Nov 1987 p 18-19.

## Chile

**084010 OPEN-SEA TERMINAL IN HOSTILE ENVIRONMENT.** A shiploading terminal near Punta Arenas, the southernmost city of the world (lat. 53°-10'S, long. 70°-54'W) is described. Strong winds, choppy seas, frequent gales, rain, and snow make it difficult to load ships at an offshore berth in this area. Detailed site investigations supplied sufficient information for the analysis of operating conditions. The results showed that a bulk loading terminal at this location is feasible, provided the design takes into consideration the specific problems of the site. Results of wind recording, statistical analysis of wind and wave data, operating criteria, and berth availability analysis are included in the paper. (Edited author abstract) 11 refs.

## Electric Lighting

**084011 SEEING IT IN A DIFFERENT LIGHT.** Today, a terminal has to offer the ability for around-the-clock working. This means good floodlighting, as no shipper is going to be attracted to facilities that cannot continue after the hours of darkness. The competitive market situation ensures a continuing striving for further efficiency in lighting design as ports themselves achieve long-term experience in night-time illumination.

## Structural Design

**084012 DESIGNING TO A FAULT.** A 30 dollars million expansion at one of the Port of Los Angeles' busiest terminals took the fast track over the Palos Verdes Fault. The seismicity of California is well known; however, setting seismic design criteria for a marine shipping facility is a major issue that is still not specifically addressed by local building codes. The design team began

by performing a probabilistic evaluation of the seismic activity expected at the facility site during an earthquake, considering all seismic sources in the Los Angeles basin. This paper describes the soil evaluation, settlement calculations and selection of pile system under horizontal seismic loads.

## Australia

**084013 PORT SAFETY DOWN UNDER.** The Australian waterfront industry shows many positive safety measures and procedures, but safety questions cannot be divorced from the broader problems of industrial relations. Statistics collected and published every six months by the training and accident prevention division of the Association of Employers of Waterside Labour (AEWL) show that in the 12 months to June 1986 a total of 4617 treatment and suspected personal injury accidents were recorded, a 10 per cent drop in two years. The AEWL also acts as secretariat to the influential Federal Advisory Committee on Waterfront Accident Prevention and Occupational Health (FAC). The general safety code to which all the ports work was compiled and issued in 1975 with FAC approval and is now in the last stages of revision. Specific guidance notes on the handling of monazite sand and uranium oxide have also been published by the FAC, as well as advice on respiratory and associated equipment for use on the waterfront. This article discusses safety training, legal position, terminal operations, and other aspects of the subject.

Compton, Mike. *Cargo Syst Int* v 15 n 2 Feb 1988 p 78-79, 81.

## Canada

**084014 PORT OF VANCOUVER: CANADA'S GATEWAY TO THE PACIFIC RIM.** The 120-year old Port of Vancouver lies in the heart of a sprawling urban area, the City of Vancouver. Today, city and port move people, traffic, and ships in a setting geared to economic growth and a cosmopolitan life style. Serving the numerous and highly varied port activities presents many ongoing challenges, not the least of which is access. Although new entrance roadways have been recently completed, access to port facilities remains an issue. Over 80% of traffic is in major bulk commodities, primarily coal, grain, forest products, sulphur, mining products, and petrochemicals. Critical to this shipping is the port's intermodal infrastructure of on-dock rail service and truck transport arteries. More than 20 specialized terminals, lining both sides of the inner harbor, are fully equipped to handle all types of bulk, general, and containerized cargo. This article surveys the port facilities in Vancouver, British Columbia, and related operational problems.

MacNaughton, Francis J. *ITE J* v 58 n 4 Apr 1988 p 21-24.

**084015 SHIP-HANDLING IN THE PORT OF CHURCHILL—THE B%EAR ESSENTIALS.** This paper describes an in-depth study performed by the authors' company to properly determine the shiphandling requirements in the Port of Churchill, on Canada's Hudson Bay, and the subsequent design and construction of the 3000-hp tugboat, H.M. Wilson. This tug is unusual primarily because of the unique and remote location of the port in which it operates, and by the limitations which this remote site placed upon its design and construction. (Author abstract). 3 Refs.

p 190-204.

## Cleaning

**084016 SCOURING THE HARBOR.** For a harbor to be maintained at a depth sufficient for handling high-tonnage ships, it must be kept clear of river silt. The traditional method of accomplishing this is periodic dredging. But dredging is an expensive operation; berths must be temporarily closed, which leads to scheduling problems with incoming vessels and to lost revenues when the terminal cannot accommodate them. Instead of dredging, a West Coast port uses a hydraulic scourjet system to wash silt away before it can settle. A digital data acquisition and control system is in charge of the operation. (Edited author abstract)

Jessen, Kenneth (Hewlett-Packard Co, Loveland, CO, USA). *Mech Eng* v 109 n 10 Oct 1987 p 46-48.

## Concrete Construction

**084017 CONCRETE IN CONSTRUCTION: LEARNING THE HARD WAY.** For many years, the north pier at the UK east coast port of Bridlington has provided a shelter for the fish quay. This regularly takes a pounding from the sea. When the authors were there, a definite swell was running against the pier, even though it was a pleasant day. It is understood that waves often break completely over the pier and the shelter: this occurrence is crucial to what happened. At a time when both paradoxically the uses of concrete are expanding whilst its limitations are being redefined, this report of one port's recent experience might prove a salutary lesson to others.

Anon. *Port Constr Ocean Technol* v 4 n 3 May-Jun 1987 p 26, 28.

## Construction

**084018 CHANNEL PORTS: STILL FIGHTING THE FIXED LINK.** Construction starts soon in earnest of the fixed link under the Channel between the UK and France. Not to be outdone, ports on both sides continue to invest heavily in development. Dover Harbor Board, set to lose most, are currently investing £1.5 million a month on civil engineering improvements. This month, construction was completed on a new number one and number three berths, and both have been designed for provide different types of facility.

Anon. *Port Constr Ocean Technol* v 4 n 5 Sep-Oct 1987 p 32, 34-36.

**084019 MINIPORT CONCEPT CUTS TIME AND COST.** The Miniport concept is basically the use of floating pontoons as quay frontage with various types of connections to shore. Several companies are offering systems that offer the advantage of considerably reducing port construction time and capital costs. (Author abstract)

Anon. *Port Constr Ocean Technol* v 4 n 2 Mar-Apr 1987 p 33-34, 36.

**084020 GO-AHEAD FINNS PLAN MAJOR PROJECTS.** With port construction currently in a very dynamic state worldwide, there is no lack of developments and ideas - some unusual - taking place. This article looks at Finland, where several construction projects are under way. (Edited author abstract)

Anon. *Port Constr Ocean Technol* v 4 n 3 May-Jun 1987 p 24-25.

**084021 AUST CONSULTANT DESIGNS TONGAN HARBOR.** Riedel & Byrne Consulting Engineers Pty Ltd is designing a new harbor for the island of 'Eua in the kingdom of Tonga. The harbor features an unusual breakwater to be constructed on top of a reef with a new vertical face. The Australian Government is providing funds for the design and supervision of construction as

part of its aid program to Tonga. The harbor works will include a new wharf, a ramp for landing barges and other craft, provision of small boat pull-out facilities, harbor excavation, breakwaters and an area of reclamation. Experimental results showed that a 2-part breakwater constructed of locally quarried 2.5 t to 3 t armor rock provided the most cost-effective solution. The breakwaters on either side of the entrance channel near the reef edge will consist of a pair of precast concrete walls grouted and bolted into the reef and infilled with armor rocks.

Dixon, Susette. *J Inst Eng Aust* v 59 n 22 Nov 13 1987 p 33.

**084022 SELF-UNLOADERS SUGGESTED AS SOLUTION TO PORT DEVELOPMENT COSTS.** A Canadian firm is marketing a bulk commodity self-unloading system which can dramatically reduce port construction costs. Construction of new bulk receiving ports can cost in the range of \$100 million, and require three to five years of lead time. Stevedoring and annual maintenance contribute further to this cost. The self-unloading system is described in the article and the advantages of the system are discussed.

Anon. *World Dredging Mar Constr* v 23 n 9 Sep 1987 p 34-35.

## Design

**084023 KALLIN HARBOUR - DESIGN AND CONSTRUCTION.** This paper describes the design and construction of a new fishing harbor which was excavated out of the rocky coastline of the Hebridean Island of Grimsay. The harbor is 25 meters wide and 32 meters long with a six meter wide slipway. The works involved the excavation of 11,000 cubic meters of rock; the formation of 1000 square meters of vertical rockface by specialized blasting techniques; the construction of 90 meters of reinforced concrete wall, eight meters high, anchored to the vertical rockfaces by resin anchors; the construction of a 35 meter long slipway; and the formation of 1600 square meters of car park and storage areas. 2 refs.

**084024 PORT & HARBOR DESIGN SIMULATOR FOR PORT & HARBOR RESEARCH INSTITUTE, MINISTRY OF TRANSPORT.** The article reports on a system manufactured for the purpose of studying the relationship between the plan of a port and ship maneuvering by integrating all IHI technologies related to ship maneuvering simulators. The system simulates the movement of its own ship and target ships based on a port design displayed graphically. The system was completed in February 1984 and is in use at present.

Matsuura, Yoshitsugu (IHI, Tokyo, Jpn); Ushio, Takao. *IHI Eng Rev (Engl Ed)* v 19 n 2 Apr 1986 p 96-98.

**084025 CARDIFF BAY BARRAGE - REMODELING FOR REGENERATION.** Cardiff Bay Development Corporation's ambitious plan to transform Cardiff into an international maritime city, hinges on the construction of a barrage across the mouth of the Bay. Stretching from Penarth Head in the west to a point adjacent to Queen Alexandra Dock in the east, the 1.2 km barrage is expected to carry high and low level sluices, locks, and probably a service road and walkways. At full tide, the barrage will create a 250 ha inland lake.

Anon. *Civ Eng (London)* Jan-Feb 1988 p 22-23.

**084026 WAVE GROUPING AND HARBOUR DESIGN.** Residual disturbances in harbors, associated with wave grouping, are discussed. The main source of energy is identified as set-down beneath wave groups, and data are provided which show the existence of set-down in the real sea; the implications for wave generation in physical models are considered. A self-consistent statistical description for responses at wave group periods is presented. This starts with a random sea in which the ordinary waves are assumed to consist of a superposition of wave components with random phases. Wave groups occur

naturally along with the associated set-down, but in physical models, compensation for set-down at the wave-maker is needed to avoid the generation of spurious long waves. Expressions for the magnitude of set-down are derived and verified experimentally in random wave flume tests. Results from a random wave physical model investigation of a proposed new harbour are used to illustrate the importance of wave grouping effects in harbour design. (Author abstract). 10 Refs.

**Dredging** See Also DREDGING; DREDGING—Costs.

**084027 DUTRA/MORRISON-KNUDSEN CONTINUE WORK ON \$12.5 MILLION MONTEZUMA SLOUGH PROJECT.** A massive control structure designed to protect the water quality of the largest brackish water marsh in the United States is being built in California by a joint venture of Dutra Construction Company and Morrison-Knudsen Company. The ambitious project involves constructing and placing a three-component gate and lock structure in the Montezuma Slough, at the upper end of the Suisun Marsh in California's Sacramento River Delta. Based upon the complex engineering and fabrication work involved in the project, it is a marine construction project with few rivals on the West Coast. The project is truly unique since the three specially designed components of the control structure were built on barges in Stockton, California, moved more than 50 miles to the Montezuma Slough, floated off the barges, and sank at the final in-service point. The Montezuma Slough project is described in detail in the article. The three major parts of the project namely dredging, concrete work and sinking are presented in detail.

Anon. *World Dredging Mar Constr* v 23 n 10 Oct 1987 p 6-11.

**084028 SAN FRANCISCO BAY DEVELOPMENT.** Author describes three navigation projects, namely Oakland Inner and Outer Harbors deepening, Richmond Harbor deepening and Sacramento Deepwater Ship Channel deepening. Disposal problems and the user fees are discussed.

Kelly, Patrick J. (US Army Corp of Engineers, USA). *World Dredging Mar Constr* v 23 n 8 Aug 1987 p 9-12.

**084029 BENEFICIAL USES OF DREDGED MATERIAL: THE WORD IS OUT.** The Corps of Engineers oversees the operation and maintenance of more than 400 U.S. ports and harbors, and 250,000 miles of inland waterways. Some 300 million cubic yards of material is dredged from these waters annually. Public Law 91-611 enacted by Congress in 1972, directed the Corps to conduct a national environmental research program on dredged material: the Dredged Material Research Program (DMRP). The five year, \$33 million program showed conclusively that 95 percent of the material dredged was uncontaminated. Today, the total amount spent by the Corps on studying the effects of dredged material disposal has reached \$100 million. Given that the vast majority of material dredged has been found not to be contaminated, dredged material can be looked upon as a valuable resource to the ecologies and economies of coastal regions. Author describes the beneficial uses of dredged material such as habitat development, beach nourishment, aquaculture, strip mine reclamation and solid waste landfill.

Anon. *World Dredging Mar Constr* v 23 n 8 Aug 1987 p 14-17.

**084030 U.S. ARMY CORPS OF ENGINEERS STEPPED UP DREDGING PROGRAM.** The waterways system is vital to the flow of the domestic and foreign commerce because it offers the cheapest and most energy efficient transport mode for such bulk cargoes as coal, grain, petroleum products, chemicals, iron and steel. In addition, the waterway system has proved to be of great

importance to our defense efforts in the past and is an essential element of our current mobilization readiness posture. The dredging program is also very important to the regional and national economies. The author describes the importance of dredging operations and the part played by US Army Corps of Engineers in the dredging program.

Murden, William R. (US Army Corps of Engineers, USA). *World Dredging Mar Constr* v 23 n 12 Dec 1987 p 6-13.

**084031 'COLUMBUS' PERFORMS MAINTENANCE JOB: B+B COMPLETES FIRST CONTRACT IN NEW YORK.** The author describes the dredge which was recently converted from a trailing suction hopper barge. This is designed for maintenance dredging as well as for aggregate dredging and beach nourishment.

Anon. *World Dredging Mar Constr* v 23 n 12 Dec 1987 p 17-18.

**084032 DREDGING PROPOSAL INTERESTS THE CORPS AND INDUSTRY.** To preclude the potential for bid unbalancing, South Atlantic Division (SAD) eliminated the allowable overdepth provision from its bid documents for maintenance dredging in June 1985. The Corps' Washington office, which currently operates with bid document regulations specifying that required dredging must be at least 50 percent of advertised quantities, approved SAD's move to more stringently control allowable overdepths, and plans to include this option in its new regulation. The South Atlantic Division hopes to show substantial cost savings through sharper competition on a fixed scope of work. The change being used by the South Atlantic Division is a logical departure from past practices. The article discusses several important issues that are brought into focus as a result of the change.

**084034 DOLLART-DOCK PROJECT EMS BYPASS AND A NEW ACCESS TO THE PORT OF EMDEN.** The increase in costs for maintenance dredging in the Port of Emden and in the seaward access, on the one hand, and the desire to improve the fairway situation, on the other hand, were decisive for the Dollart-Dock-Project (DDP). Since the middle of the sixties, the Port of Emden planning staff has developed a port extension plan. It is foreseen to bypass the river Ems through the Dollart-bay and to block up the Emden-fairway on downstream and upstream sides. The new access to the Port of Emden will be 10 km seawards the old sea lock, nearby Knock-landmark. Nearly 67 mill. m<sup>3</sup> of different kinds of soil is to be dredged in the bypass and to be used or setting up a new sea dyke. The rest is to be deposited on a disposal areas in the estuary. A new sea lock for ocean-going vessels up to 150,000 dwt and an inland navigation lock are to be built. (Author abstract) 3 refs.

## Federal Republic of Germany

**084035 STANDORT HAMBURG-SERVICE IM BE-REICH DES SEEVERKEHRS.** [Maritime-Transport-Related Service Based in Hamburg]. Hamburg, the largest seaport of the Federal Republic of Germany is not only an important place of transshipment for West German imports and exports but, due to its geographical location, one of the most important European transit ports. Approx. 15,000 ships call at Hamburg each year. Over 40 PERCENT of the total maritime-transport-related cargo transshipment volume (approx. 140 million tons) of the Federal Republic of Germany is handled via Hamburg. In German.

Hoffmann, Hans-Joachim (Blohm & Voss AG, Hamburg, West Ger). *Thyssen Tech Ber* v 20 n 1 1988 p 69-73.

## Fire Protection

**084036 FRESH LOOK AT SHIP AND PORT FIRE-FIGHTING.** The article is a resume of a study report on the title subject. The original report was written by Michael Charles, of Trinidad and Tobago, following a visit to the United Kingdom and to whom a Commonwealth and Overseas Fire Services Association (COFSA) scholarship was awarded. Subjects covered include ships types and materials, warning systems, fire-fighting planning, fire-fighting equipment, at-sea and in-port fire-fighting, and others. 6 Refs.

Charles, Michael. *Fire Int* v 12 n 111 Jun 7 1988 p 58-59.

France See CLAY—Consolidation.

Goderich, Ontario See PIERS—Repair.

## Great Britain

**084037 MULTI-MILLION POUND INVESTMENTS IN UK SOUTH COAST PORTS.** From Newhaven to Falmouth the ports on England's south coast are investing vast sums in a bid to remain competitive, avoid stagnation and capture a greater share of available trade. This article reports on individual developments. (Edited author abstract).

Stevens, Barrie. *Dock Harbour Auth* v 68 n 800 Apr 1988 p 299-301.

## Hong Kong

**084038 TOLO HARBOUR - THE CASE FOR INTEGRATED WATER QUALITY MANAGEMENT IN A COASTAL ENVIRONMENT.** Tolo Harbour (Hong Kong) is a marine inlet which is under severe development pressure. Degradation of the environment has caused visual nuisance, adverse ecological changes, economic losses, and health risks. The increasing occurrence of damaging and potentially dangerous red tides is closely correlated with the increase in nutrient pollution loading. This comes mainly from two sewage treatment works, even though they are performing in accordance with their design. The Hong Kong Government's response involves a co-ordinated sequence of conventional pollution control activities. The problems which are now being faced would not be so severe if earlier planning and given adequate recognition to the ecological consequences of all the aspects of development in combination. (Author abstract) 13 refs.

Holmes, Paul R. (Environmental Protection Dep, Hong Kong). *J Int Water Environ Manage* v 2 n 2 Apr 1988 p 171-179.

## Inspection

**084039 COMPUTERISING UNDERWATER INSPECTION.** It is now possible for ports to go one step further and adopt the most up-to-date method of maintenance control by investing in a micro-based computer system for running all phases of subsea inspection and maintenance work. This is the aim of Transcon, London-based consultants specializing in detailed planning and management of underwater inspection programs using a unique program called SIMMS. The 'Structural Inspection and Maintenance Management System' can be tailored to individual needs, is menu driven, has ready access to historical data and is transportable for immediate on-site control.

Anon. *Port Constr Ocean Technol* v 4 n 5 Sep-Oct 1987 p 20-21.

## Japan

**084040 LOOKING TO THE FUTURE WITH LAND FROM THE SEA.** Port projects in Japan are so huge that even though they are no longer just about ports, but about a full range of civic functions, they still involve a massive increase in cargo handling capacity. Kobe's 'Renaissance' project has three aspects, all due for completion by 1995. The centrepiece of Yokohama's development is the Minato Mirai 21 (MM21) project, meaning future port for the 21st century, due for completion in 2000. The three aspects form the subject of this article.

Champion, Vincent. *Cargo Syst Int* v 14 n 8 Aug 1987 p 28-29.

## London, England

**084041 REORGANISATION AT THE PORT OF LONDON.** Organizational changes designed to improve the Port of London's efficacy and competitiveness became fully operational in 1987. The management of London's main activities has been devolved into separate operational units so that performance in individual sections can be measured. This is the first time that business units within the Port of London Authority (PLA) have been able to identify and develop their own commercial ventures. The author evaluates the effectiveness of the organizational changes in relation to the performance of the various areas of operation.

Stevens, Barrie. *Dock Harbour Auth* v 68 n 798 Feb 1988 p 239-242.

Maintenance See DREDGING.

## Management

**084042 STRATEGIES FOR SUCCESS.** Small ports can be divided into two basic categories: Those which cater for a single commodity or handle traffic for a single user; and those operated as general cargo and common user facilities. The ownership of the port will have a significant bearing on the type of facility provided but irrespective of ownership, effective planning and management are essential to the successful operation of any small port. The small port has to base future strategies on sound research which will then be used to determine how the port facilities could be developed to maximize returns. The various factors which will influence future strategies include: Commodities and anticipated parcel size; Commodities and anticipated parcel size; determination of the port's hinterland and an examination of the inland transport system; physical limitations on vessels using the port; an analysis of total transport costs to the shipper/-consignee; and available finance. These and other aspects of the subject are discussed.

Anon (Ocean Mackenzie Ltd, Woking, Engl). *Cargo Syst Int* v 14 n 10 Oct 1987 p 87, 89.

## Mathematical Models

**084043 CORPUS CHRISTI INNER HARBOR SHOALING INVESTIGATION.** A combination of numerical models was used to test alternatives for shoaling prevention in Corpus Christi Harbor, Texas. The vertically averaged model system, TABS-2, was used to simulate contributions of sediments by bay waters to the sediment load. The laterally averaged estuarine model,

LAEMSED, was used to simulate density currents in the channel and sedimentation that occurs at the harbor entrance. Applications of the models testing advance maintenance, removal of industrial discharges and withdrawals, advance maintenance in conjunction with a sill, and movement of the disposal areas showed a 20 percent decrease in shoaling as a result of industrial activity removal, a 75 percent decrease in sediments entering the bay channel due to disposal area relocation, and practically no effect on shoaling rates resulting from advance maintenance. (Edited author abstract) 20 refs.

Smith, Tamsen M. (US Army Corps of Engineers, Vicksburg, MS, USA); McAnally, William H. Jr.; Teeter, Allen M. *Tech Rep US Army Eng Waterw Exp Stn HL-87-13* Sep 1987 var pagings.

New Zealand See Also WATER POLLUTION—Analysis.

**084044 PORT SAFETY THE NEW ZEALAND WAY.** Waterside workers are administered by the Waterfront Industry Commission (WIC). Employers belong to the New Zealand Association of Waterfront Employers (NZAW). Safety is inextricably linked with each of these various strands and an important element is the Waterfront Training Organization (WTO). Founded in 1968 as a separately funded division of the NZAW, the WTO is recognized as one of the nation's Industry Training Boards. This article discusses legal considerations, compensation, safety organization, applications, and other aspects of the subject.

Compton, Mike. *Cargo Syst Int* v 15 n 1 Jan 1988 p 64-65, 67.

## Northern Ireland

**084045 MAIL QUAY DEVELOPMENT AT LARNE HARBOUR.** In September 1985, the Board of Larne Harbour Ltd, recognizing that the existing Mail Quay, equipped with an aged narrow single deck vehicle ramp (which had steep operating gradients and a maximum safe working load of 32 t) was too short and shallow for modern ro/ro vessels, decided to upgrade the structure. Work began in 1986 and the quay was commissioned in October 1987. A brief description of the work involved in the upgrading of Larne's Mail Quay is presented. (Edited author abstract)

Anon. *Dock Harbour Auth* v 68 n 798 Feb 1988 p 244-245.

## Oakland, California

**084046 RECENT DEVELOPMENTS AT THE PORT OF OAKLAND.** The attitude of the Oakland Port Authority is that ports must be even more competitive than shipping companies as clients have the choice of taking their shipping elsewhere. Accordingly, Oakland is taking energetic steps to upgrade its terminals and intermodal facilities within the port area, enter into joint-venture programs with rail and ocean carriers in order to improve bridge and tunnel access hundreds of kilometres from the port, and to market its advantages aggressively to those who make the real decisions. This article reviews some of the projects that the Port of Oakland is undertaking.

**Protection** See SONAR—Military Applications.

**Sedimentation** See BREAKWATERS—Design.

**Sweden**

**084049 PICKING PRIORITIES.** Sweden's ports provide diverse answers to diverse cargo handling requirements and are constantly trying to widen their cargo base. The Port of Goteburg, Scandinavia's leading ro-ro and container port, exemplifies this approach. One of its key projects is known as 'SKT 90', meaning 1990 as the deadline for commissioning all new handling traffic management systems at the Skandiahamnen container/ro-ro terminal. To date most attention has focused on the equipment aspects, in particular new quayside and yard cranes and the phased introduction of straddle carriers. The decision to introduce straddle carriers was based on the assessment that modern straddles are efficient transporters as well as lifters. Given Goteburg's established consultancy work in different parts of the world, it could well be of major long-term significance to manufacturers in this sector. This and other Swedish ports, cargo handling equipment, and management are discussed.

Champion, Vincent. *Cargo Syst Int* v 15 n 2 Feb 1988 P 45, 47.

**084050 PROFITABLE LINKS?** The explosion in ferry and ro-ro capacity in Sweden's ports creates important new opportunities for landbridge operations, yet may not have such negative consequences for lo-lo handling as is commonly supposed. Shipping line executives have been surprised by the apparent enthusiasm with which Swedish ports have chased new ferry links with Denmark, East and West Germany and other Baltic areas. Flexi and fixed links as well, may bring new opportunities to expand their total traffic base. Already Stockholm has witnessed a 50 per cent increase in throughput at the Baltic Ferry Terminal, opened only last year. This article discusses market conditions, management, and other factors related to the development of ferry links among Swedish shippers.

Champion, Vincent. *Cargo Syst Int* v 15 n 2 Feb 1988 P 49, 51.

**United Arab Emirates**

**084051 PORT WORKS AT FUJAIRAH, UNITED ARAB EMIRATES.** Construction of a new deepwater port at Fujairah on the east coast of the United Arab Emirates on the Gulf of Oman commenced in 1979; the port began operating in 1983. The paper discusses the considerations in choosing a suitable site and the investigations and planning for an artificial harbor within two major breakwaters extending 1 1/2 km. offshore into natural water depths of 15 meters, allowing for final provision of ten deepwater and two shallow water berths. It describes the design and construction of the port works

in the initial phase of development including the rock-filled concrete-dolosse-armored breakwaters, two deepwater container berths in mass concrete slice work with extensive areas of pre-cast blockwork paving for general cargo and container handling and storage, and ancillary facilities. (Edited author abstract) 3 refs.

**Wales**

**084052 WELSH WIZARD.** A small yet ambitious multi-purpose port project is gradually taking shape in Pembroke Dock, West Wales. The main quay will offer a depth alongside of 10.8 m below chart datum at any state of the tide, and the facilities will be open round the clock. The development is being both executed and managed by the Govan Davies Group (GDG). There are 150 acres available for warehousing, open storage or offshore gear fabrication either within the dock perimeter or immediately adjacent to it. This includes two former Sunderland Flying Boat hangars, located behind the main quay, each offering 3750 m<sup>2</sup> of storage and a clear working height of 18 m, with full opening 13.5 m x 49 m doors. Even more land is available for stockholding or other port-related duties within a five mile radius of the dock area. The new deep water port, scheduled for completion towards the end of this year, will provide almost 400 m of continuous quay frontage.

**Wave Effects**

**084053 NUMERICAL MODELLING OF HARBOUR WAVE DISTURBANCE IN COMPARISON WITH PHYSICAL MODELLING AND FIELD MEASUREMENTS.** This paper describes the results of numerical modeling of wave disturbance in the harbor of Ronne, Denmark, using the hydrodynamic modeling System 21 of the Danish Hydraulic Institute. The name of the system indicates that it can be applied to unsteady 2-dimensional flow in 1 layer. It includes the so-called 'Boussinesq' terms, which account for the deviation from hydrostatic pressure distribution caused by the vertical accelerations. It can simulate the phenomena of diffraction, refraction, reflection, and shoaling of natural irregular waves in a harbor of arbitrary shape and bathymetry. Comparisons have been made between the disturbance coefficients of numerical modelling and those of physical modeling and also between the former and those of field measuring data. The results indicate that there is in general a good agreement between them. (Author abstract) 5 refs.

**Wilmington, Delaware**

**084054 OVERVIEW OF WILMINGTON HARBOR SOUTH PROJECT.** A 2440-m long dredged material disposal area containment embankment averaging 3.65 m in height is being constructed at Wilmington, Delaware. The construction is accomplished using high strength geotextiles as tensile reinforcement over a foundation consisting of soft, weak silts and clays forming the tidal flats and shallows of the Delaware River at the site. Vertical strip drains are used to speed the consolidation of the upper 7.3 m of the foundation soils to allow completion of the second stage of the embankment construction within a reasonable (12 to 18 month) time period. The embankment fill is hydraulically placed and the two stage construction is required to complete the embankment to its full height without risking failure of the foundation materials. Design features and construction methods, along with problems encountered to date are addressed. (Author abstract). 5 Refs.

**POSISTORS**

**Materials**

**084055 TRENDS IN PTC RESISTOR TECHNOLOGY.** Positive temperature coefficient (PTC) resistors have been in widespread use since 1965 in automotive, home appliance, telecommunication and industrial applications. They are used as self-regulating heaters, current limiters, overcurrent protectors, and sensors. Recent progress in PTC resistor technology includes the development of materials with transition temperatures exceeding 300C, improved microstructures with greater resistance to degradation, new device shapes useful in heater applications and a better understanding of the PTC mechanism. Piezoresistive properties have been more fully characterized. New ceramic materials have been explored. Polymer composite PTC resistors have been introduced for heater and current overload protection applications. These developments are reviewed. The stability of both types of resistor is compared, and the advantages of each are discussed. (Edited author abstract) 39 refs.

**Prefabrication**

**084057 NEW POST OFFICE AND TELECOMMUNICATIONS HEADQUARTERS IN DUESSELDORF.** The new building, rising in the center of the town, houses one of the most important telecommunications plants. The formal aspect can be envisaged as a compact parallelepiped volume, 6 floors in height and rectangular, 57 m x 74 m, in plan. The load-bearing structure is in situ cast reinforced concrete and is formed by a central core with columns and beams at the perimeters. The floor structures consist of joists at 55 cm centers topped with a concrete slab. The facades are entirely prefabricated using various types of concrete units which can be subdivided into three different groups according to their dimensions and finish characteristics. All the exposed surfaces are characterized by the red granite Odenwalder aggregate employed. (Author abstract) In Italian and English.

**POTASH**

**Agricultural Applications**

**084058 REVIEW OF AGRICULTURAL DEVELOPMENTS IN POTASH USE.** Efforts to develop potash use in agricultural production were begun in the US 50 years ago. Early growth was rapid and continued well into the 1960s. Many soils were inherently low in K, so crop responses to fertilization were often dramatic. Deficiency symptoms were common. Per-acre use has continued to increase in recent years, but annual growth rates have slowed. Soil buildup has occurred in some

areas. Poor economics in the 1980s have been difficult to overcome. Efforts are now under way to develop potential markets around the world. (Edited author abstract) 9 refs.

## POTASH DEPOSITS

Saskatchewan, Canada

**084059 SASKATCHEWAN POTASH: NEAR-TERM PROBLEMS, LONG-TERM OPTIMISM.** Canadian Potash Export Ltd. (Canpotex) was created in 1970 as the offshore marketing organization for Canadian producers. Canpotex is owned by Saskatchewan producers and is their exclusive marketing organization for offshore business. The Saskatchewan industry has an ore body of a size and consistency unmatched anywhere in the world. Large efficient mines have production costs that costs that compare favorably with other producing countries. On the minus side, Saskatchewan is remote from most major markets. It therefore needs the efficiencies that stem from one organization that coordinates all offshore shipments and minimizes distribution costs.

Flooding

**084062 ALBERTA'S GEOTECHNOLOGY: OIL KNOWHOW HELPS THE POTASH AND HARD-ROCK MINERS.** The Rocanville study was performed to plot overlying areas of potentially hazardous brine solutions. This followed PCS Rocanville's successful handling of the underground flood which occurred between November 11, 1984 and January 24, 1985. Consultants used oil technology seismic reflection geophysics;

work was also done using a radar survey of the salt back. The new pulseEKKO III ground penetrating radar technology is the electromagnetic analog of the seismic reflection method.

Hopkins, John L. *Can Min J* v 108 n 9 Sep 1987 p 23-27.

Grouting

**084063 ERGEBNISSE INGENIEUR-GEOLOGISCHER KLÜFTUNTERSUCHUNGEN IM SALINAR FUER ABDICHTUNGSINJEKTIONEN VON ZUFLUESSEN IM KALIBERGBAU DER DDR.** [Results of Engineering-Geological Studies of Fractures in the Salt Body for Grouting of Inflows in GDR Potash Mining by Injections]. A sound knowledge of the structural-geological conditions of the salt body is an important prerequisite to successful grouting of water and brine inflows in salt mining by injections. In this paper, a primarily rock-dependent jointing of sulfate and carbonate layers of the Upper Permian is proven and quantified. The influence of the depth, the development of tectonic stress and other influence factors on the formation and intensity of the jointing in the Upper Permian salt body are discussed. The jointing models established by engineering-geological methods are the basis for a decision aimed at obtaining an efficient and economically favorable control of inflows by injections. (Edited author abstract) 50 refs. In German.

Staubert, Axel. *Freiberg Forschungsreihe A* n 753 1988 p 1-59.

Management

**084064 BOULBY POTASH MINE.** Beleaguered by problems in its early days, Cleveland Potash Ltd's Boulby mine has overcome earlier setbacks and is now running at a profit. The development plan called for the sinking of two shafts; the construction of a totally enclosed finished product silo; and onsite process plant with two stacks. Owing to the situation of the site - 3 km within the boundaries of a national park - Boulby was one of the first mines to conform to 'modern' planning requirements. For instance, the site was to occupy an area of old iron ore workings, and transport by rail direct to Teeside was specified for some 75% of the potash, on 9 km of reinstated railway track, previously closed by British Rail in 1958.

Planning See MINE SHAFTS—Lining.

Productivity

**084065 AUX MINES DE POTASSE D'ALSACE, COMMENT ENCORE PROGRESSER APRES LES AMELIORATIONS DE PRODUCTIVITE DES DIX DERNIERES ANNEES? [How to Make Further Progress at the Potash Mines of Alsace After the Productivity Advances of the Past Ten Years].** During the last ten years, the productivity progress of the potash mines of Alsace originated substantially, on the one hand, from the modernization and the adaptation of the long-wall faces with full-face shearing to all heights of the seam, and, on the other hand, from the concentration of the production in two establishments. In two areas (full-face shearing and haulage), programmable automation or systems with microprocessors have been installed. The improvement of the performances of the next few years will come from the development of these systems. (Edited author abstract) In French.

Rock Bursts

**084066 MULTIDIMENSIONAL STATISTICAL MODEL FOR THE REGIONAL PREDICTION OF DISCHARGE HAZARD OF POTASH ROCK.** The discharge-hazard factor currently determines, to a considerable extent, the technical principles and organizational

and economic aspects of the working of potash deposits. This factor must be taken into account in designing potash mines, in proceeding to the development of new levels, and in the operation of working sections. Information on the discharge hazard of potash rock provides the economic basis for the construction of potash mines, taking account of the use of counterejection measures. 4 refs.

Waste Disposal

**084067 MODELLING OF FLOW THROUGH POTASH TAILINGS PILES.** Modelling the flow of brine through potash tailings requires that the saturated and unsaturated hydraulic properties of the tailings be established; in particular, the relationships of fluid content and permeability to matrix suction are required. The in situ and laboratory testing techniques used for determining these properties are described and the results are presented. Numerical modelling techniques for the flow of brine through potash tailings are demonstrated by performing a computer simulation of an open-trench infiltration test. The responses of the field instrumentation during the infiltration test were compared with the results of the simulation. The simulation utilizes the measured fluid content versus suction curves and the calculated permeability versus suction curves as input parameters. The effects of varying the hydraulic properties of the tailings are examined to arrive at a better understanding of the flow mechanism involved. (Edited author abstract). 23 Refs.

## POTASH ORE TREATMENT

Decomposition

**084068 UNDERGROUND DISSOLUTION OF SYLVINITE. SEARCHING FOR AN EFFECTIVE METHOD OF TREATING THE PRODUCTION SOLUTIONS.** It is shown that the solution of the problem of more rapid mastery of the method of underground liquefaction of sylvinites depends decisively on finding an effective method of treating the extracted brines. One of the interesting proposals for treating sylvinites brines is a method based on successive precipitation of sodium and potassium bicarbonates by carbonization of sylvinites brine in the presence of organic analogs of ammonia (amines and imines), in particular, hexamethylenimine or hexamethylenediamine. Because of some problems with this method, the authors propose a method of simultaneous precipitation of sodium and potassium bicarbonates by carbonization in the presence of hexamethylenimine. In Russian. 6 refs.

## Condensation

**084070 EXPERIMENTAL STUDY ON POTASSIUM CONDENSATION.** The objective of the present study is to clarify the characteristics of metal condensation. In the present study, highly accurate measurements of condensation rate, condenser surface temperature and vapour pressure are rendered possible. In addition to the techniques for these measurements, the vacuum distillation method is adapted to ensure that the results are not affected by the presence of non-condensable gases. The conformity in the vapour flow field of the present apparatus to previous analyses is also assured. Measurements are made by using potassium for a vapour temperature range from 553 K to 633 K. It is found that the present result is in agreement with the analysis of Labuntsov and Kryukov and the condensation coefficient is very close to unity. It is also concluded that Schrage's theory predicts higher condensation rates than those in actual cases. (Author abstract) In Japanese. 14 refs.

## Isotopes

**084073 AUTOMATED PRODUCTION OF POTASSIUM-38 FOR THE STUDY OF MYOCARDIAL PERFUSION USING POSITRON EMISSION TOMOGRAPHY.** The  $^{35}\text{Cl}(\alpha,n)$  reaction on sodium chloride has been selected for the rapid and reproducible production of  $^{38}\text{K}$  for repeated heart studies by means of positron emission tomography. A simple automated ra-

diochemical system has been developed and tested which makes routinely available 10-12 mCi batches of  $^{38}\text{K}$  ready to be injected at successive intervals of time of 40 min. The number of i.v. injections is only limited by the acceptable total absorbed dose to the patient. This limitation could be substantially reduced by using more recent multislice positron cameras which show better detection efficiency and resolution. 30 refs.

**Molten** See Also COAL—Alkylation.

**084074 SOLUBILITY OF OXYGEN IN LIQUID POTASSIUM.** The solubility of oxygen in liquid potassium has been determined in the temperature range of 343 to 675 K. Equilibration experiments were carried out in a nickel-lined stainless steel solubility vessel with samples being withdrawn through a nickel filter of porosity 5  $\mu\text{m}$ . The oxygen content of the filtered sample was determined by the vacuum distillation method. A least-squares fit of the solubility data yielded the following equation:  $\log C (\text{ppm}) = 3.9702 - 420.4/T(\text{K})$ . The heat of solution derived from this expression is  $8047 \text{ J mol}^{-1}$ . The new solubility equation has been utilized to calculate oxygen potentials in liquid potassium and threshold oxygen levels for the formation of  $\text{KCrO}_2$  on a stainless-steel surface exposed to liquid potassium at high temperatures. (Author abstract) 10 refs.

## Phase Diagrams

**084075 ON THE SLOPES OF PHASE BOUNDARIES.** Several simple equations are derived which can be used to check binary phase diagrams for thermodynamic consistency. In many cases, the only thermodynamic data required are the entropies of fusion. (Author abstract). 10 Refs.

Pelton, Arthur D. (Ecole Polytechnique de Montreal, Montreal, Que, Can). *Metall Trans A* v 19A n 7 Jul 1988 p 1819-1825.

**084076 CRITICAL ASSESSMENT OF THERMODYNAMIC PROPERTIES AND PHASE-DIAGRAM CALCULATIONS OF K-KCl AND K-KBr SYSTEMS.** All the available thermodynamic information on the K-KCl and K-KBr systems has been collected and used, through an optimisation procedure, to check the thermodynamic consistency of those experimental thermodynamic data. Optimized sets of parameters for the excess Gibbs energy of mixing of the K-KX liquid solutions have been obtained; the liquid phase was modelled as a simple mixture of K and KX, exactly equivalent to a 'sublattice' type model, the excess Gibbs energies being represented by Redlich-Kister polynomials. Agreement between calculated and experimental phase diagrams and thermodynamic functions is within the experimental uncertainties. (Author abstract). 23 Refs.

## Structure

**084077 ELECTRONIC STRUCTURE OF POTASSIUM AND METAL HALIDE GICs STUDIED BY ANGLE-RESOLVED X-RAY EMISSION SPECTROSCOPY.** Angle-resolved C K-emission bands of the donor-GICs  $\text{C}_8\text{K}$  and  $\text{C}_{24}\text{K}$ , of acceptor compounds intercalated with  $\text{AlCl}_3$ ,  $\text{FeCl}_3$ ,  $\text{SbF}_3$ ,  $\text{SbCl}_5$ ,  $\text{BiCl}_3$ ,  $\text{InCl}_3$

and of different species of pure graphite have been measured using synchrotron radiation for excitation. Decomposition of the emission bands into the  $\pi$ - and  $\sigma$ -subbands provides insight into the modification of the  $\pi$  and  $\sigma$  electron density of states of graphite by intercalation. The  $\pi$ - and  $\sigma$ -band of the potassium-GICs are considerably changed. In the  $\pi$ -band new states arise near the Fermi energy  $E_F$ . For the metal halide-GICs the observed changes which we relate to charge transfer are smaller and restricted to the high energy part of the  $\pi$ -band. (Author abstract) 10 refs.

**084081 ORIENTATION DEPENDENCE OF THE CARBON K-EDGE IN THE ELECTRON ENERGY LOSS SPECTRA OF A POTASSIUM-BENZENE-GRAPHITE INTERCALATION COMPOUND.** Electron energy loss spectra of the carbon K-edge region in graphite and the first-stage potassium-benzene-graphite intercalation compound (GIC) have been measured as a function of the crystal orientation defined by the angle between the crystal c-axis and the incident electron beam direction. The intensity of the carbon  $1s \rightarrow \eta^*$  transition peak strongly depends on the crystal orientation. The dependence for potassium-benzene-GIC differs from that for graphite. By analyzing the orientation dependence of the  $1s \rightarrow \eta^*$  transition intensity observed in potassium-benzene-GIC, it is found that the molecular plane of benzene intercalating between the graphite layers is tilted relative to the crystal c-axis. (Author abstract) 18 refs.

**084082 OBSERVATION OF A PRESSURE INDUCED REVERSE PEIERLS INSTABILITY IN THE QUASI-ONE-DIMENSIONAL MIXED VALENCE SOLID  $K_4 [Pt_2(P_2O_5H_2)_4Br] \cdot 3H_2O$ .** The pressure dependence of the resonance Raman and UV-visible absorption spectra of the quasi-one-dimensional mixed valence solid  $K_4 [Pt_2(P_2O_5H_2)_4Br] \cdot 3H_2O$  has been observed. The band maximum of intervalence-charge-transfer (IVCT) transition red shifts from 620 to 740 nm as pressure is increased from 0.0 to 4.0 GPa and then levels off. Resonance Raman spectra obtained with excitation into the IVCT band show a continuous decrease in the scattering intensity of the Pt-Br symmetric stretch and one of the Pt-Ft stretches as pressure is increased and neither mode can be observed above 4.0 GPa. These results are attributed to a structural change where the Br ion moves toward a central position between neighboring Pt<sub>2</sub> moieties along the chain axis, as is consistent with a reverse Peierls transition. **084083 KINETICS OF INTERACTION OF GLASERITE WITH CALCIUM NITRATE SOLUTION.** The authors report a study of the kinetics of interaction of glaserite of mono- and polydisperse composition with calcium nitrate solution at 25-80°. It is shown that the process includes formation of an intermediate product, syngenite, which passes into gypsum at 80°. It is also shown that difficultly soluble reaction products crystallize both in the bulk solution and on the surface of the glaserite particles, where they form a gradually thickening crust whose porosity varies with time and which hinders free diffusion of the reactants. The thickness of this crust as a function of temperature was calculated theoretically and measured experimentally. 6 refs.

**084085 STAGE DEPENDENCE OF ELECTRONIC STATES IN POTASSIUM GIC BY X-RAY ABSORPTION NEAR EDGE POLARIZATION-DEPENDENT STRUCTURE (XANEPS) MEASUREMENTS.** The x-ray absorption, near edge polarization-dependent structure measurements have been carried out for several stages of potassium intercalation compounds of graphite. The dependence of the structure on polarization has been interpreted using the calculated band structure and the symmetry of the wave-functions at potassium site. Based on the dependence of the location of absorption edge on stage as well as the case of fully ionized potassium, it is concluded that the charge transfer in  $KC_8$  is nearly total. **084086 USE OF SIMILARITY OPERATORS FOR LATTICE-SUPERLATTICE RELATIONS: I. APPLICATIONS TO MONOCLINIC AND ORTHORHOMBIC FLUORITE-RELATED STRUCTURES.** Similarity operators are shown to relate the lattice vectors and origins of the structure and the superstructure, the symmetry operators of the space group  $G$  of the structure to those of the subgroup  $H$  of  $G$  of the superstructure, and finally those atomic positions which are conserved in the superstructure. In the monoclinic and orthorhombic fluorite-related structures of composition  $K_{0.5-x}Ln_{0.5+x}F_{2+2x}$  ( $Ln = \text{lanthanide and Y}$ ) considered here we find that the cation sublattice is conserved. The origin of the superstructure does not necessarily coincide with the origin of the structure, but is a point of high site symmetry. (Author abstract) 7 refs.

**Crystallization**

**084087 CRYSTALLIZATION KINETICS OF POTASSIUM CHLORIDE FROM BRINE AND SCALE-UP CRITERION.** In this paper a three-year study on the kinetics of potassium chloride crystallization from brine is reported. This work was done in two analogous mixed-suspension, mixed-product-removal (MSMPR) crystallizers, one of 2.5 dm<sup>3</sup> volume and the other of 25 cm<sup>3</sup>. The constant tip speed TIPS was found to be the scale-up criterion, and the hydrodynamic conditions can be defined by a group  $M_T(\text{TIPS})^3$ . The nucleation rate and growth rate correlated well with this group in a general kinetic equation. 143 tests were made to obtain satisfactory standard deviations of all power indexes and the coefficient in the general kinetic equation. (Edited author abstract) 19 refs.

**084088 CRYSTALLIZATION OF POTASSIUM TITANATE FROM THE AMORPHOUS PHASE.** By using amorphous potassium titanates as the starting materials, a sintered body of  $K_2Ti_4O_9$  or  $K_2Ti_6O_{13}$  with porous and fibrous textures was prepared.  $K_2Ti_2O_5$  and a new phase,  $K_6Ti_4O_{11}$ , were synthesized by the thermal reaction of  $KNO_3$  with  $TiO_2$  at 1000°C for 10 to 20 h. On leaching in water to expel excess potassium ions, both phases became amorphous. After mixing and moulding these materials in the desired proportion, a sintered body containing fibrous crystals of  $K_2Ti_4O_9$  was fabricated by heating at 1000°C for 12 h. When 5 wt%  $B_2O_3$  was added, single phase  $K_2Ti_6O_{13}$  with a fibrous texture grew on heating at 1000°C for 12 h. Addition of PVA polymer to the amorphous phases was responsible for controlling the porosity of the sintered body, about 52% theoretical density at 20 wt% PVA polymer. The optimum conditions for preparing the amorphous phases were examined and the effect of the chemical reaction environments such as different crucible materials on the calcination of  $KNO_3$  and  $TiO_2$  is discussed. (Author abstract) 8 refs.

**Deformation**

**084090 ELECTROPLASTIC EFFECT IN  $Ca^{2+}$ -DOPED KCl SINGLE CRYSTALS.** The application of electric fields up to 6 MV m<sup>-1</sup> reduces the flow stress during constant-strain-rate deformation of KCl containing 90 mol.p.p.m.  $Ca^{2+}$ . These stress drops have been measured for various magnitudes and directions of electric field. It was found that the amount of stress drop is dependent on the component of electric field along the direction of Burgers vector. These effects are quantitatively interpreted by the charge-dislocation model which was first proposed by Whitworth in 1976 and which is modified in this paper. The charge values estimated in this model are  $2.8 \times 10^{-1}$  for a rapidly cooled crystal and  $1.9 \times 10^{-10} \text{Cm}^{-1}$  for a slowly cooled crystal. (Author abstract) 22 refs.

**084091 IONIC THERMOCURRENTS DUE TO Z-CENTRES IN  $KCl:Gd^{2+}$ .** The technique of ionic thermocurrents (ITC) was used to study the field-induced reorientation of electric dipoles in crystals of  $KCl:Gd^{2+}$ . Besides the peak at 240 K due to impurity-vacancy (I-V) dipoles, a new peak is observed at 213 K which can be attributed to  $Z_1$ -centers. This supports a model involving an F-center coupled to an I-V dipole. No new ITC peak was observed in crystals containing  $Z_2$ -centers. (Author abstract) 16 refs.

**084092 ON THE ANALYSIS OF THE IONIC THERMOCURRENT SPECTRUM.** Dielectric relaxation parameters are usually evaluated from the ionic thermocurrent (ITC) spectrum following the method suggested by C. Bucci et al. However, the BFG method becomes ineffective in the cases where either the background current is not estimated correctly or multiple relaxation processes are present. In the latter case, the method suggested by the author can be followed which utilizes the heating rate dependence of the peak and the position of the ITC maximum. Although this method is theoretically sound, it fails to give satisfactory results when applied to actual experimental systems. A modification is proposed to meet this inability. 5 Refs.

**084094 CONDUCTIVITIES OF MOLTEN MIXTURES OF POTASSIUM FLUORIDE OR CHLORIDE WITH HAFNIUM TETRAFLUORIDE.** The authors describe results obtained when studying the conductivity of molten  $\text{KF-HfF}_4$  and  $\text{KCl-HfF}_4$  mixtures. It is shown that when hafnium tetrafluoride is added to melts of potassium fluoride or chloride the self-complexation present in these melts is disrupted and new complex forms based on the hafnium ion arise which have a rather higher ionic moment and larger polarizing power. The hafnium ion coordinates the fluoride and chloride ions, and the potassium ions are crowded out to the second coordination sphere. In melts of the  $\text{KF-HfF}_4$  system containing insignificant charge transport are elemental potassium ions of the second coordination, complex potassium ions, and the complex hafnium ions  $\text{HfF}_7^{3-}$  and  $\text{HfF}_6^{2-}$ . 4 refs.

**084095 SLIDING CHARGE DENSITY WAVES WITHOUT DAMPING: POSSIBLE FROHLICH SUPERCONDUCTIVITY IN BLUE BRONZE.** We observed zero differential resistance in  $\text{K}_{0.3}\text{MoO}_3$  in the temperature range of 4.2-40 K. It appears above a contact dependent barrier voltage. At 4.2 K the current can be increased from 50 nA to 1A without observable change in voltage. By measuring narrow band noise spectra at different current levels we show that the phenomenon arises from undamped sliding of charge density waves. (Author abstract) 15 refs.

Mihaly, G. (CNRS, Grenoble, Fr); Beauchene, P. *Solid State Commun* v 63 n 10 Sep 1987 p 911-914.

**084096 CHARGE-DENSITY WAVE CONDUCTION WITH EXTREMELY LOW DIFFERENTIAL RESISTANCE IN  $\text{K}_{0.3}\text{MoO}_3$ : CURRENT OSCILLATIONS.** We have studied the real time current oscillations in the low temperature zero differential resistance state of blue bronze ( $\rho_{\text{diff}} < 10^{-4} \Omega\text{cm}$ ), where the current

increases more than seven orders of magnitude without observable change in the voltage. The linear relation between the oscillation frequency and the current as well as the pulse duration memory effect observed demonstrate that the electronic transport is due to the charge-density waves (CDW). The drift velocity of the condensate reaches values as large as a few hundred cm/sec, leading to a metallic conductivity in an 'insulating' medium at  $T=4.2$  K. The drop of the CDW damping reflects the qualitative change in the conduction mechanism as normal carriers freeze out. (Edited author abstract) 25 refs.

**Electric Field Effects**

**084097 PHOTOLUMINESCENCE OF  $\text{KTaO}_3$  UNDER ELECTRIC FIELD.** The photoluminescence in undoped  $\text{KTaO}_3$  crystal has been measured under static electric fields at 49 K. When a voltage is applied to the crystal, the intensity of the blue emission band decreases, and the emission spectrum becomes a yellow emission band. It is shown that these effects are caused by an increase of the temperature in  $\text{KTaO}_3$  as a result of Joule heating. (Author abstract) 23 refs.

**Electric Properties** See Also SODIUM COMPOUNDS—Electric Properties.

**084098 JOULE HEATING AND BREAKDOWN EFFECTS IN  $\text{KNO}_3$  THIN LAYERS.** The current-voltage (I-V) characteristics of  $\text{KNO}_3$  single crystal thin layers of the thickness range 35 to 145  $\mu\text{m}$  have been studied and the critical voltage  $V_c$  and breakdown voltage  $V_b$  determined. Experimental evidence for the existence of Joule heating has been found. A semi-theoretical approach to the data involving a law of cooling has enabled the activation energy associated with the current increase to be estimated and found to be  $\phi = 0.05$  eV. The effect of externally heating the layer indicates a change in the layer current at  $T_c = 130^\circ\text{C}$ . This suggests phase changes and is supported by differential thermal analysis. It is concluded that the I-V characteristics are influenced by Joule heating which causes changes in the  $\text{KNO}_3$  phase. A discussion is given on which type and mechanism of electrical breakdown is present. (Edited Author abstract) 23 refs.

**Granulation**

**084101 STUDY OF GRANULATION OF POTASSIUM SALTS WITH THE AID OF ROLLS WITH A RIFFLED SURFACE.** The dependence of the density of powdered materials on the average normal stress determines their compactability. It is possible with the aid of diagrams for compaction of powders to estimate the influence of the physical and mechanical properties of the original salt and to determine the compactability coefficients and the specific work of pressing of materials to a specified final density. Compactability diagrams of fine-grained potassium chloride were obtained with the aid of a PMM-125 hydraulic press and a cylindrical mold 36 mm in diameter. Curves for variation of the density of flotation potassium chloride with the load at final pressures from 40 to 200 MPa are given. The diagram can be used for determining the specific work of compression of the powder to a specified final density, which is needed for calculation of the power consumption of roll-press drives. The authors devise a method for calculating, with adequate accuracy for practical purposes, the output rate and the power consumption of presses with riffled rolls; this is of considerable interest for development of new high-capacity roll presses for granulation of mineral salts and fertilizers. 6 refs.

**Heat Transfer**

**084102 RADIATIVE HEAT TRANSFER IN MOLTEN POTASSIUM NITRATE AND GLASSY MELTS OF BORIC OXIDE.** A model for radiative-convective heat transfer at high temperatures in molten potassium nitrate and boric oxide is proposed which takes into account recent experimental determination of the absolute values of absorption coefficients in the infrared. Corrections for radiative heat transfer in the thermal conductivity data reported by several authors are suggested and, it is shown that the great uncertainty in the thermal conductivity data is partly due to underestimation of the radiative transfer. For molten potassium nitrate the conclusions is that its thermal conductivity is independent of temperature. In contrast, the temperature coefficient of thermal conductivity of boric oxide is positive. (Edited author abstract) 13 refs.

## Impurities

**084105 X-RAY INDUCED RELAXATION BAND DUE TO HIGHER AGGREGATES IN KCl:Pb.** Although aggregation of impurity centers in doped alkali halides upon X-irradiation is proposed earlier, direct evidence of such centers having dipole moment is reported here for the first time by the method of ionic thermocurrents (ITC). The normal dipolar relaxation band in KCl:Pb is located around 224 K, while sometimes a small band at about 160 K is found in the ITC spectrum of heavily doped systems. Exposure to X-rays increases this band around 160 K at the cost of the 224 K dipolar band. Optical absorption in the A-band of KCl:Pb, along with ITC measurements indicates that higher aggregates of I-V dipoles are easily formed in heavily doped systems. Formation and growth of the 160 K ITC band upon X-ray irradiation are explained. (Edited author abstract) 7 refs.

Mukherjee, M.L. (Univ of Parma, Parma, Italy); Capelletti, R. *Phys Status Solidi B* v 142 n 2 Aug 1987 p 361-366.

**084106 PHYSICO-CHEMICAL PROPERTIES OF  $Dy^{3+}$  IN SINGLE  $KY(MoO_4)_2$  CRYSTAL (ELECTRON ABSORPTION, EMISSION, IR, RAMAN, AND MAGNETIC DATA).** Electron absorption, luminescence, vibrational, and magnetic properties of  $KDy_xY_{1-x}(MoO_4)_2$  crystals are examined over the entire concentration region  $x = 0$  to  $x = 1$  and a temperature range 13-293 K. The crystal field scheme of the  $^6H$ ,  $^6F$ ,  $^4F$ ,  $^4I$  manifolds and their Stark components are established. The  $\tau_\lambda$  Judd-Ofelt parameters are determined by the numerical method and related to the concentration effect. The temperature dependence of the lifetime of luminescence is discussed and a quenching mechanism is proposed. (Author abstract) 21 refs.

Hanuzza, J. (Polish Acad of Sciences, Wroclaw, Pol); Macalik, L.; Ryba-Romanowski, W.; Mugenski, E.; Cywinski, R.; Witke, K.; Piltz, W.; Reich, P. *J Solid State Chem* v 73 n 2 Apr 1988 p 488-501.

**084107 OBSERVATION OF ABSORPTION AND SUBSEQUENT LUMINESCENCE FROM THE RELAXED EXCITED STATE OF  $Sn^{2+}$  IN KI.** By pump-probe experiments, an absorption from an excited state of the  $Sn^{2+}$  impurities in KI and subsequent luminescence at 445 nm was found. Time-resolved, phase sensitive measurements showed that this absorption took place from the relaxed excited state, related to the  $A_1$ -luminescence, to a short-living ( $\tau < 15$  ns) energy level from which radiative decay at 445 nm occurred. This luminescence could not be reproduced by one photon irradiation in any of the A, B and C absorption bands of isolated  $sn^{2+}$  impurities in KI. The intensity and the decay time of the luminescence can be accounted for by the temperature dependence of the lifetime of the relaxed

excited state. (Edited author abstract). 7 Refs.

## Ionic Conduction

**084108 IONIC CONDUCTIVITY IN KBr IRRADIATED AT ROOM TEMPERATURE.** There are different points of view to explain the effect of radiation on the ionic conductivity. A new model has been proposed by J. Vignolo and J.L. Alvarez Rivas to explain the effect of radiation on the ionic conductivity in KCl crystals irradiated at room temperature. These authors found that some radiation-induced damage partly inhibits the dipole dissociation. A step to gain support for this model is to determine whether or not the phenomenology of the radiation-induced ionic conductivity in KBr crystals also fits into the model. This is the purpose of this work. In this letter a study of radiation-induced effect on the ionic conductivity of pure KBr crystal and its thermal stability is presented. 9 refs.

**084112 COMPARATIVE STUDY OF THE MAGNETIC AND ELECTRICAL PROPERTIES OF PE-**

**ROVSKITE OXIDES AND THE CORRESPONDING TWO-DIMENSIONAL OXIDES OF  $K_2NiF_4$  STRUCTURE.** Experimental results show that (i) Perovskite oxides which are ferromagnetic in three dimensions do not show long-range ferromagnetic ordering in the corresponding two-dimensional oxides. This behavior is observed in both itinerant and insulating oxide systems. (ii) The magnetic susceptibility behavior of these oxides in the high-temperature region is not affected by changing the dimensionality. The observed changes in paramagnetic Curie temperature is consistent with the reduction of the number of nearest neighbors. (iii) Oxides which are metallic in three dimensions with a resistivity less than that corresponding to the 'minimum metallic conductivity' ( $2 \times 10^{-3}$  ohm cm) show a negative TCR in two dimensions with a resistivity always higher than  $10^{-2}$  ohm cm. 25 refs.

**084113 PREPARATION OF HIGH PURITY POTASSIUM SILICATE.** High-purity potassium silicate finds extensive use as an adhesive of phosphors in television receiver screens. Ammonium silicate is prepared from sodium silicate with the help of cation-exchange resin in ammonium form. Effect of concentration of sodium silicate on the breakthrough capacity of the resin is studied. Exhausted resin was efficiently regenerated with 2.0 N solution of ammonium salt. Silica was precipitated from ammonium silicate with concentrated solution of ammonium salt. (Edited author abstract) 18 refs.

## Microscopic Examination

**084114  $K_5Nb_9W_2O_{31}$ : A NEW TETRAGONAL-TUNGSTEN-BRONZE-RELATED STRUCTURE, DEDUCED FROM HREM IMAGES.** High resolution electron microscopy (HREM) and X-ray powder-diffraction studies of samples in the K-Nb-W-O system revealed a new type of tetragonal-tungsten-bronze (TTB) related structure of the general composition  $A_xM_{11}O_{31}$ . The parent TTB has the unit cell content  $K_{6-x}W_{10}O_{30}$ , with potassium occupying four- and five-sided tunnels. In the present structure,  $K_5Nb_9W_2O_{31}$ , as in many of its relatives, some of the five-sided tunnels are filled with strings of -M-O-M-O- ( $M = Nb, W$ ) and have thereby been transformed into pentagonal columns (PCs). The PCs are mutually diamond-linked to form slabs. (Edited author abstract) 15 refs.

## Microstructure

**084115 SYNTHESIS OF NEW PHASES,  $K_2MXO_4$  ( $MX = BeSi, MgGe, CaSi, CdGe$  AND  $ZnSi$ ).** Within the families of stuffed silica structures, there exist several phases which are face centered cubic and appear to be stuffed cristobalite phases. The structures are presumed to be three-dimensional frameworks built of corner-sharing tetrahedra, with the alkali ions occupying large interstitial sites within the framework. This letter reports the synthesis and preliminary characterization of other new phases which appear also to be stuffed cristobalite-like phases. These are listed, together with their refined unit cell parameters and melting behavior. Indexed X-ray powder diffraction patterns are also given. 8 refs.

## Optical Properties

**084116 GROWTH AND EVALUATION OF LARGE KDP SINGLE CRYSTALS FOR HIGH-POWER HARMONIC GENERATION BY TEMPERATURE DECREASE METHOD.** In the growth of KDP single crystals by the temperature decrease method, the dimensions of equipment for the growth of the crystal whose dimensions are desired for type I and type II phase matching of SHG are discussed, where the (001) plate and (101) plate are used as seed crystals, respectively. It is shown that the equipment has the smallest dimensions in the growth of the crystals for type II with the seeds of the (101) plate. Then the large crystals are grown with the seeds of the (101) plate and their optical characteristics are described. (Author abstract) 5 refs.

**084117 ACCURATE VALUES FOR THE INDEX OF REFRACTION AND THE OPTIMUM PHASE MATCH PARAMETERS IN A FLUX GROWN KTiOPO<sub>4</sub> CRYSTAL.** Precise values of refractive indices, measured by the auto-collimation method, are presented in this paper. The phase match parameters of a KTP crystal at 1.064  $\mu\text{m}$  were calculated, and from these were obtained the optimum phase match parameters,  $\theta = 90^\circ$ ,  $\Phi = 23.6^\circ$ , with an effective non-linear coefficient  $1.75 \times 10^{-8}$  esu. This is the best agreement with an experimental result ever reported. (Author abstract) 6 refs.

**084118 VIBRATIONAL PROPERTIES OF THE Ga<sup>0</sup> AND In<sup>0</sup> CENTERS OF THE Ti<sup>0</sup> (I) STRUCTURE AS STUDIED BY RESONANT RAMAN SCATTERING.** The Raman scattering spectra of M<sup>0</sup>(I) centers (M = Ga, In, and Ti) in KCl, which possess the laser-active type structure, have been resonantly excited in their third optical transitions (OT<sub>3</sub>). The low frequency resonances at 59, 45, and 30  $\text{cm}^{-1}$ , respectively, are attributed to the totally symmetric motion of the impurity atom along the fourfold axis in the C<sub>4v</sub> point group of the defects. The spectral distribution of the defect-induced first order phonon spectrum is remarkably similar for the three centers, showing that it essentially reflects the motion of the surrounding ions. The Raman spectrum of In<sup>0</sup>(I) in NaCl almost exclusively consists of the fundamental vibration of In<sup>0</sup> and its overtones. A correspondence is indicated between this discrete character of the Raman spectrum and the electronic properties of the M<sup>0</sup>(I) defects in the NaCl host lattice. (Edited author abstract) 18 refs.

Joosen, W. (Univ of Antwerp, Wilrijk, Belg); Sierens, C.; Schoemaker, D. *Solid State Commun* v 63 n 1 Jul 1987 p 69-72.

**084119 ON THE SKEWNESS OF THERMALLY STIMULATED LUMINESCENCE PEAKS.** The skewness of numerically computed thermally stimulated luminescence (TSL) peaks with various values of order of kinetics (b),  $0.8 \leq b \leq 2.2$ , were investigated for a particular value of b the skewness is a function of  $E/kT_m$ . First-order (b = 1) TSL peaks are characterized by negative skewness, whereas second-order (b = 2) ones show positive skewness. These results are utilised to determine the order of kinetics of some typical first-order (b = 1) and second-order (b = 2) TSL peaks from their skewness. The experimental measurements were performed on X-irradiated Ca doped KCl. (Edited author abstract) 7 refs.

Hakeem, S.A. (Manipal Univ, Imphal, India); Gartia, R.K. *Phys Status Solidi A* v 106 n 2 Apr 1988 p 635-640.

**084120 CROSS LUMINESCENCE OF KF AND RELATED COMPOUNDS.** The luminescence of KF, KMgF<sub>3</sub>, KCaF<sub>3</sub>, and solid solutions KF-RbF was studied under excitation with 6 keV electron pulses. Electronic

transitions from the F<sup>-</sup> 2p valence band to the K<sup>+</sup> 3p core band result in a specific 'crossluminescence' in the 6-9 eV region with decay time <2 ns. In the KF-RbF solid solutions the transitions from the F<sup>-</sup> 2p valence band to the Rb<sup>+</sup> 4p localized states or to the corresponding impurity band gives rise to luminescence bands at 5.4 and 6.1 eV as in pure RbF. (Author abstract) 18 refs.

**084121 DECREASE OF THE TL GLOW PEAK TEMPERATURE BY PARTIAL CLEANING.** An interesting phenomenon is observed for a thermoluminescence (TL) glow peak of an additively colored and X-irradiated KCl:Cu, Cs single crystal. The peak temperature decreases by performing the partial cleaning. This is out of our common sense, because it is expected that a lower temperature TL peak should decay earlier than higher ones when they are overlapping. As the result, the composite peak should shift to the higher temperature side. A tentative calculation is performed to explain the effect assuming the transfer of electrons from one type of traps to the other during the TL. (Author abstract) 4 refs.

**084122 OPTICAL ABSORPTION AND EMISSION FROM Ho<sup>3+</sup> IONS IN KCaF<sub>3</sub> CRYSTALS.** The optical absorption, emission, and excitation spectra are reported for KCaF<sub>3</sub>:Ho<sup>3+</sup> crystals. The Ho<sup>3+</sup> ions evidently occupy only one site in this lattice. The measured oscillator strengths for several transitions are compared with values calculated from Judd-Ofelt theory and the calculated radiative rates are also tabulated. The temperature dependence of the lifetimes suggests that energy transfer occurs between Ho<sup>3+</sup> ions at concentration levels of 1.3 at. percent. (Author abstract) 35 refs.

**084123 XPS STUDY OF THE KCl SURFACE OXIDATION IN OXYGEN GLOW DISCHARGE.** The reaction between the surface of KCl and oxygen in a glow discharge has been studied by X-ray photoemission spectroscopy (XPS). Oxygen glow discharge treatment resulted in the formation of a superoxide, which decomposed under vacuum at room temperature to KO<sub>2</sub> and finally to K<sub>2</sub>O. No evidence of KClO<sub>3</sub> or KClO<sub>4</sub> formation has been found. Binding energies of some oxygen species in potassium oxides were determined. The possible role of potassium in K-doped silver catalysts of ethylene epoxidation is discussed. (Author abstract) 25 refs.

## Phase Transitions

**084124 BRILLOUIN, RAMAN AND LIGHT DIFFRACTION STUDY OF PHASE TRANSITIONS IN KLiSO<sub>4</sub> UNDER A UNIAxIAL STRESS.** The phase transitions between 150 and 300 K in KLiSO<sub>4</sub> are studied under an applied stress through the simultaneous observation of Raman and Brillouin spectra and of the diffraction of light by the domain walls. Three distinct phases are identified; it is proved that between 190 and 265 K the sample can consist of the mixing of two phases; the ferroelastic behavior of the low-temperature phase (T < 190 K) is confirmed and the orientations of the

related domain walls are defined. (Author abstract) 27 refs.

**084125 OPTICAL STUDIES ON THE ORTHORHOMBIC-CUBIC TRANSITIONS FOR KClO<sub>4</sub>, RbClO<sub>4</sub> AND CsClO<sub>4</sub>.** An optical investigation of the high-temperature structural transitions in gel-grown single crystals of KClO<sub>4</sub>, RbClO<sub>4</sub> and CsClO<sub>4</sub> is reported. These crystals undergo transitions from the room-temperature Pnma phase to a cubic Fm3m phase at T<sub>c</sub> values of 306°C, 281°C and 222°C, respectively. The birefringence  $\Delta n$  falls abruptly to zero at T<sub>c</sub>, as is expected in a first-order transition. The phase transition was also studied by measuring the intensity of light transmitted by the sample placed between crossed Nicol prisms. The results do not suggest the coexistence of phases above T<sub>c</sub>. Microscopy examination of the samples at transition reveals that on cooling from the high-temperature phase the crystals have a tendency to form multidomains, with differing orientations, in the orthorhombic phase. (Edited author abstract) 14 refs.

**084126 PREMARTENSITIC PHASE IN KAlF<sub>4</sub>: NEUTRON AND X-RAY SCATTERING EVIDENCES.** From elastic neutron scattering experiments, it is shown that the anomalies which have been recently observed in the high temperature phase of KAlF<sub>4</sub> by the x-ray mono-Laue technique can be attributed to embryonic domains of a premartensitic phase which coherently coexists with the high temperature phase. The arrangement of the domains and the lattice parameters of the premartensitic phase are determined. On the basis of geometrical considerations and with regard to the two-dimensional character of this layered compound we propose a possible structure for the premartensitic phase. The coexistence of the two phases can be interpreted by means of edge dislocations which are presumably formed during the crystal growth procedure. The role played by the premartensitic phase on the onset of the KAlF<sub>4</sub> martensitic transformation is discussed. (Author abstract) 28 refs.

Gibaud, A. (Univ du Maine, Le Mans, Fr); Bulou, A.; Le Bail, A.; Nouet, J.; Zeyen, C.M.E. *J Phys (Paris)* v 48 n 9 Sep 1987 p 1521-1532.

**084127 CRYSTAL OPTICAL STUDIES OF THE PHASE TRANSITIONS IN KLiSO<sub>4</sub>.** The sequence of phases and transition temperature of KLiSO<sub>4</sub> - hexagonal I (948 K) orthorhombic II (711 K) hexagonal III (205 K) trigonal IV (185 K) monoclinic V (83 K) VI (65 K) VII (38 K) VIII - was investigated using microscopically resolved measurements of linear birefringence (LB), refractive indices and optical activity (OA). Principal results are: (i) orthorhombic stripe domains intersecting under  $\pm 120^\circ$  in the C plane characterize phase II; (ii) vanishing LB and residual OA hint at merohedrally twinned 3m symmetry in phase IV; (iii) none of the phases V thru VIII is axial; (iv) observation of three pairs of twin domains refute orthorhombicity of phase V. (Author abstract) 17 refs.

**084128 ENERGY TRANSFER IN MONOCRYSTALLINE KCl DOPED WITH EUROPIUM AND MANGANESE.** Fluorescence intensity and lifetime measurements of the Eu<sup>2+</sup> and Mn<sup>2+</sup> emissions have been carried out in single crystals of KCl doped with europium and manganese ions. The data obtained indicate

that sensitized luminescence with the europium ions as sensitizers and the manganese ions as activators occurs between  $\text{Eu}^{2+}$ - $\text{Mn}^{2+}$  pairs which are formed in this material. The number of these pairs are, however, smaller than those which are formed in the lattice of NaCl. The calculations based on the Forster-Dexter model of energy transfer indicate that the observed fast rise time of the manganese fluorescence after pulse excitation of  $\text{Eu}^{2+}$  can only be explained if a short range interaction mechanism such as electric dipole-quadrupole or exchange in nature is active. (Edited author abstract) 10 refs.

## Production

**084129 PREPARATION OF POTASSIUM TETRAFLUOROBORATE ENRICHED WITH BORON-10 OR BORON-11 ISOTOPES.** A new method is proposed in this study for the preparation of potassium tetrafluoroborate by the conversion of boron trifluoride into potassium tetrafluoroborate which includes the reaction of boron trifluoride with an aqueous solution of potassium fluoride. The theoretical yield of the potassium tetrafluoroborate according to the above scheme does not exceed 94% (without accounting for the losses with the mother liquor), excluding the participation of the hydrofluoric acid which is formed in one reaction. In another reaction where fluoroboric acid is formed, as expected in such a case, part of the boric acid does not take part in any further reactions and remains unconverted into the fluoroboric acid, reducing the yield of the potassium tetrafluoroborate. The synthesis conditions described in this work enable one to obtain potassium tetrafluoroborate of 99.0% purity and in 98.0% yield. 7 refs.

**084130 ESR STUDY OF X-IRRADIATED  $\text{KNO}_3$ .** Single crystals of  $\text{KNO}_3$  were irradiated with X-rays at room temperature, and ESR measurements were performed over the temperature range from 85 K to 400 K. The g and hyperfine tensors of some paramagnetic centers were determined, and it was concluded that  $\text{F}$ ,  $\text{O}_2^-$ ,  $\text{O}_3^-$  and  $\text{NO}_2$  centers were produced. The sites and orientations of  $\text{O}_2^-$ ,  $\text{O}_3^-$  and  $\text{NO}_2$  molecules in a  $\text{KNO}_3$  crystal were also determined. The superhyperfine interactions of F and  $\text{O}_2^-$  centers with adjacent  $^{14}\text{N}$  and  $^{39}\text{K}$  nuclei were investigated, and the superhyperfine components were determined. Further, isothermal annealing measurements were performed for the F and  $\text{O}_3^-$  centers. (Author abstract) 15 refs.

**084131 IDENTIFICATION OF A PARAMAGNETIC  $\text{Bi}^{0+}$  CENTER IN X-IRRADIATED  $\text{KCl}:\text{Bi}$  CRYSTALS.** Crystals of KCl doped with bismuth exhibit after X-irradiation at room temperature the presence of a paramagnetic defect with tetragonal  $<100>$  symmetry. Based on the analysis of the ESR spectra a structural model based on a  $\text{Bi}^{0+}$  atom center is proposed. The strong axial crystal field is due to the presence of a vacancy in the first neighborhood and/or a static Jahn-Teller distortion of  $\text{E}_g$  character. (Author abstract) 16 refs.

## Reaction Kinetics

**084133 KINETIC STUDY OF ELECTROCHEMICAL INTERCALATION OF POTASSIUM SOLVATED BY TETRAHYDROFURAN INTO GRAPHITE.** The formation of ternary graphite intercalation compounds  $\text{K}(\text{THF})_x$  approximately 2 C approximately  $20\text{H}$  has been followed by neutron diffractometry during cathodic intercalation of  $\text{K}^+$  ( $\text{THF}$ )<sub>y</sub> into a HOPG electrode. The pure first stage appears only after the formation of transient phases from about 4th stage towards the second. All the phases are constituted with organic molecules 'standing up' between graphene layers. For the first time in the study of ternary compounds, a new phase of stage 4/3 has been observed for cation concentrations ranging from the second stage stoichiometry to the first one. It corresponds to highly ordered stacking domains consisting of 66% stage 1 and 33% stage 2. (Author abstract) 9 refs.

Marcus, B. (Ecole Natl Supérieure d'Electrochimie et d'Electrometallurgie de Grenoble, St.-Martin-d'Heres, Fr); Touzain, Ph. *Synth Met* v 23 n 1-4 Mar 1988, Graphite Intercalation Compd, Proc of the Fourth Int Symp, Jerusalem, Isr, May 24-29 1987 p 13-17.

## Recovery

**084134 POSSIBILITIES OF RECOVERING POTASSIUM SALTS FROM BITTERN BY METHANOL PRECIPITATION.** Bittern is treated with methanol in order to study the possibility of selective crystallization of a potassium salt by the salting out effect. It is shown that at low methanol concentrations the only solid phase obtained is NaCl. At moderate methanol concentrations sodium potassium sulfate and sodium magnesium sulfate double salts crystallize together with NaCl. When the methanol to bittern volume ratio is higher than one, solid phases are composed of sodium sulfate, potassium sulfate and NaCl. Sodium sulfate percentage in the solid phases is always dominant. Potassium salts in bittern are materials of interest to Turkey since there is no known potash ore reserve. Potassium salts are used mostly as fertilizer and are totally imported. (Edited author abstract) 5 refs.

Nusret Bulutcu, A. (Istanbul Technical Univ, Istanbul, Turk); Tolun, Rasit. *Bull Tech Univ Istanbul* v 38 n 3 1985 p 313-324.

## Reduction

**084135 KINETICS AND MACROKINETICS OF THE HIGH-TEMPERATURE REDUCTION OF POTASSIUM SULFATE BY HYDROGEN. III. REDUCTION BY A MIXING OF STEAM AND HYDROGEN.** A study was carried out on the reduction of solid potassium sulfate ( $d \approx 50 \mu\text{m}$ ) by a mixture of hydrogen and water vapor at 1073 K initial temperature and atmospheric pressure. An increase in  $\text{H}_2\text{O}$  at 35 kPa leads to an increase in the liberation and integral yield of  $\text{H}_2\text{S}$  as well as the conversion of  $\text{K}_2\text{SO}_4$  to  $\text{KOH}$ . A drop in the yield of  $\text{H}_2\text{S}$  and extent of reduction is found at higher  $\text{P}_{\text{H}_2\text{O}}$ . The proposed model for the reduction of  $\text{K}_2\text{SO}_4$  by hydrogen was extended to the case of the hydrogen-steam mixture and the nonisothermal nature of this process was considered. The calculated differential and integral curves for the liberation of hydrogen sulfide were in satisfactory accord with the experimental data for the  $\text{P}_{\text{H}_2\text{O}}$  range studied (from 0 to 46.7 kPa). (Author abstract) 5 refs.

## Research

**084136 SOLVENT EFFECTS ON THE REDOX POTENTIALS OF POTASSIUM 12-TUNGSTOSILICATE AND 18-TUNGSTODIPHOSPHATE.** To our knowledge, hexacyanoferrate (III) and hexacyanomanganate (III) are the best representative cases for the study of solvent effects on redox potentials of anions. To enlarge examples in this field, it is shown here that two heteropolyacid potassium salts,  $\alpha\text{SiW}_{12}\text{O}_{40}\text{K}_4$  and  $\alpha\text{P}_2\text{W}_{18}\text{O}_{62}\text{K}_6$ , as studied by slow sweep rate cyclic voltammetry, undergo reversible or quasi-reversible reduction in several solvents. The specific interactions between solvents and the nitrogen atoms of the hexacyano complexes are replaced by interactions with oxygen atoms. The redox potentials, in the present cases, are also found to be functions of the acceptor number of the solvents. (Author abstract) 14 refs.

Keita, B. (CNRS, Nancy, Fr); Bouaziz, D.; Nadja, L. *J Electrochem Soc* v 135 n 1 Jan 1988 p 87-91.

**Solubility** See Also PHOSPHORIC ACID.

**084137 SOLUBILITY IN THE SYSTEM  $\text{K}_2\text{SO}_4\text{-H}_2\text{SO}_4\text{-H}_2\text{O}$ .** The purpose of this work was to study equilibrium in the system  $\text{K}_2\text{SO}_4\text{-H}_2\text{SO}_4\text{-H}_2\text{O}$  at temperatures of 75 and 90°C. Study of solubility in this system in relation to conversion of potassium chloride with sulfuric acid in aqueous solution is linked with the fact that the system  $\text{KCl-H}_2\text{SO}_4\text{-H}_2\text{O}$  becomes a nonequilibrium system at sulfuric acid concentrations above 50 mass % and temperatures above 75°. Solubility in the system  $\text{K}_2\text{SO}_4\text{-H}_2\text{SO}_4\text{-H}_2\text{O}$  at 75 and 90° was studied, and the presence of the following solid phases was established:  $\text{K}_2\text{SO}_4$ ,  $\text{K}_3\text{H}(\text{SO}_4)_2$ ,  $5\text{K}_2\text{SO}_4\text{-3H}_2\text{SO}_4\text{-2H}_2\text{O}$ , and  $\text{KHSO}_4$ . The existence of the double acid sulfate  $5\text{K}_2\text{SO}_4\text{-3H}_2\text{SO}_4\text{-2H}_2\text{O}$  at 75 and 90° between tripotassium hydrogen bis(sulfate) and potassium hydrogensulfate was demonstrated. Points lying in the region of the molten hydrate  $\text{K}_2\text{SO}_4\text{-3H}_2\text{SO}_4\text{-H}_2\text{O}$  were found on the 90° isotherm; potassium hydrogensulfate is present in the solid phase in equilibrium with the melt. 11 refs.

Buksha, S.V.; Sokolov, I.D.; Kopylev, B.A.; Buksha, Yu.V. *J Appl Chem USSR* v 59 n 10 pt 1 Oct 1986 p 2072-2076.

**084138 CHANGE OF SOLUBILITY OF POTASSIUM SULFATE IN WATER CAUSED BY TRACES OF CHROMIUM(III).** The solubility of potassium sulfate in water is shown to be decreased by a trace (up to 150 ppm) of chromium(III) added as green sulfate ( $\text{Cr}_2(\text{SO}_4)_3\text{-4H}_2\text{O}$ ). The proposed mechanism for the impurity action is that an adsorbed layer of chromium(III) on the surface of the dissolving potassium sulfate crystals stops their dissolution and prevents the solution concentration from reaching the true equilibrium value. The measured solubility in the presence of chromium(III), therefore, is only an apparent solubility and is always lower than the true equilibrium solubility. Its actual value is probably determined by two competing rate processes: adsorption of chromium(III) and dissolution of potassium sulfate crystals. This mechanism offers a reasonable explanation of the experimental results on the 'solubility'. (Edited author abstract) 6 refs.

**084139 STANDARD pH VALUES FOR POTASSIUM HYDROGENPHthalate REFERENCE BUFFER SOLUTIONS IN ACETONITRILE-WATER MIXTURES UP TO 70 WT% AT VARIOUS TEMPERATURES.** Reference value standards, pHs, for 0.05 mol kg<sup>-1</sup> potassium hydrogenphthalate (KHPH) reference buffer solutions in 30, 50 and 70 wt% acetonitrile-water mixed solvents at temperatures from 288.15 to 308.15 K have been determined from emf measurements of the reversible cell Pt|Ag|AgCl|KHPH+KCl|Quinhydrone|Pt, in which the H<sup>+</sup>-reversible quinhydrone electrode replaces the ill-behaving hydrogen electrode. Values of the first ionization constant of the o-phthalic acid (H<sub>2</sub>Ph; benzene-1,2 dicarboxylic acid) in these mixed solvents have also been determined from analogous measurements. The consistency of the present results with the previously determined pHs values in 5, 15 and 30 wt% acetonitrile-water mixtures is analysed by multilinear regression of pHs as a function of both solution composition and temperature. (Edited author abstract) 14 refs.

**084143 VISCOSITY, DENSITY, AND ELECTRICAL CONDUCTIVITY OF K<sub>4</sub>P<sub>2</sub>O<sub>7</sub> SOLUTIONS.** The density, viscosity, and electrical conductivity at 293-363 K of solutions having X<sub>4</sub>P<sub>2</sub>O<sub>7</sub> concentrations of 0.007-0.91 kmole/m<sup>3</sup> were studied using water thermo-

statting to an accuracy of ±0.1. It is found that the decrease in the activation energy of viscous flow for 10<sup>-3</sup>-10<sup>-2</sup> mole/kg of water may be associated with the destructive action of the ions, while for higher concentrations and with a decrease in the size of the charge on the ions due to the formation of anions of the type P<sub>2</sub>O<sub>7</sub><sup>4-</sup> and a weakening of their electrostatic interaction it may be associated with the ionic atmospheres and the neighboring water molecules. The decrease in the activation energy of viscous flow with an increase in temperature and the change in the values of η<sub>sp</sub> is explained. 5 refs.

### Spectroscopic Analysis

**084144 LOW TEMPERATURE RAMAN SPECTRA OF KLiSO<sub>4</sub>.** Raman experiments have been performed on KLiSO<sub>4</sub> below room temperature. In the intermediate temperature range (190 K < T < 265 K), the spectra are better understood on the basis of the C<sub>3</sub> rather than C<sub>6</sub> point group, but a lower symmetry cannot be rejected. In the low temperature region (T < 190 K) the occurrence of three ferroelastic domains should be taken into account to explain the corresponding Raman spectra. (Author Abstract) 14 refs.

Kihal, B. (CNRS, Villetaneuse, Fr); Dugautier, C.; Farhi, R. *Solid State Commun* v 62 n 5 May 1987 p 373-377.

**084145 VIBRATIONAL SPECTRA OF THE LAYERED COMPOUNDS K<sub>3</sub>Sb<sub>2</sub>M<sub>2</sub>O<sub>14</sub>·xH<sub>2</sub>O (M = P, As): NORMAL COORDINATE ANALYSIS OF K<sub>3</sub>Sb<sub>3</sub>P<sub>2</sub>O<sub>14</sub>·xH<sub>2</sub>O.** Infrared and Raman spectra on powder samples of K<sub>3</sub>Sb<sub>3</sub>P<sub>2</sub>O<sub>14</sub>·xH<sub>2</sub>O and K<sub>3</sub>Sb<sub>3</sub>As<sub>2</sub>O<sub>14</sub>·xH<sub>2</sub>O and polarized Raman spectra on a single crystal of K<sub>3</sub>Sb<sub>3</sub>P<sub>2</sub>O<sub>14</sub>·xH<sub>2</sub>O have been recorded. A normal coordinate analysis using a generalized valence force field has been performed. All the normal modes of vibration are described in terms of potential energy distribution. The validity of the force field and the values of the force constants are discussed. (Author abstract) 14 refs.

**084146 STRUCTURE IN THE TEMPERATURE DEPENDENCE OF THE LIFETIME OF THE EXCITED F-CENTER IN KCl.** Evidence of a temperature-dependent structure in the lifetime of excited F-centers in KCl is reported. The sharp features are revealed when the temperature control of the sample is better than a few hundredth of a degree. For less accurate temperature control, as currently used in lifetime measurements, sharp variations of the lifetime with temperature are averaged, and the structure is not detectable. A theoretical explanation is suggested. (Author abstract) 9 refs.

**084147 EMISSION AND EXCITATION SPECTRA FROM DIVALENT Ge IONS IN KCl SINGLE CRYSTALS.** The emission from KCl:Ge<sup>2+</sup> excited in the A-absorption band was studied as a function of temperature. The A-band excitation produces complex emission from KCl:Ge<sup>2+</sup>, compared with ones from Ti<sup>3+</sup>-like ions with the s<sup>2</sup> electronic configuration. The A-band emissions from KCl:Ge<sup>0</sup> and KCl:Ge<sup>4+</sup> were also measured at low temperature. The analysis of these spectra indicates that the two low-energy emission bands of KCl:Ge<sup>2+</sup> which peaked at 515 and 675 nm, respectively, are to be attributed to divalent Ge ions. The definitive assignment of the two bands is presented in terms of the adiabatic potential energy surface (APES). (Author abstract).

**084158 STRUCTURE OF LOW-TEMPERATURE IR ABSORPTION SPECTRA OF KCl AND KBr**

**CRYSTALS WITH  $NO_2^-$  AND  $NO_3^-$  ANION IMPURITIES.** The structure of the IR absorption of KCl and KBr crystals doped with the MA  $NO_2^-$  and  $NO_3^-$ , both additionally doped and not doped with  $Ca^{2+}$  and  $Ba^{2+}$  cations, were studied. The complicated structure of the spectra, which is most distinct at low (4.2-77K) temperatures, was interpreted; it was found that complexes of the impurity MA  $NO_2^-$  and  $NO_3^-$  with  $Ca^{2+}$  and  $Ba^{2+}$  cations form. The structure of the complexes formed and the local symmetry of the MA in such complexes are discussed. 12 refs.

Boiko, V.V.; Kushnirenko, I.Ya.; Shinkarenko, V.K.; Shcherbatskii, V.P. *J Appl Spectrosc* v 46 n 5 May 1987 p 462-466.

**084159 ENDOR STUDY OF  $Ni^{2+}$  IN  $KMgF_3$ .** An ENDOR study of cubic  $Ni^{2+}$  ions in  $KMgF_3$  is presented. The superhyperfine (SHF) interaction with second shell fluorine ions is found to have axial symmetry, the values of the isotropic and anisotropic interaction constants being  $a = 0.36 \pm 0.03$  MHz and  $b = 1.02 \pm 0.03$  MHz. A calculation of these SHF parameters has been performed assuming that the lattice is undistorted around  $Ni^{2+}$  and using a simple overlap model. The calculated values agree within 15% with the experimental ones. (Author abstract) 11 refs.

Zorita, E. (CSIC, Zaragoza, Spain); Alonso, P.J.; Alcalá, R.; Spaeth, J.M.; Soethe, H. *Solid State Commun* v 66 n 7 May 1988 p 773-775.

## Stresses

**084160 TEMPERATURE DEPENDENCE OF THE EFFECTIVE STRESS FOR KCl SINGLE CRYSTALS.** The authors have proposed a method which is based on the Blaha effect which is the phenomenon that the flow stress decreases by superposition of an ultrasonic oscillatory stress during plastic deformation. Using the new method they separated the effective stress from the applied one for KCl crystals. The ratio of the effective stress to the applied one at 77 K is larger than that at higher temperatures. This leads to a difference between the temperature dependences of  $m^*$  and  $m$ . The value of  $m$  at room temperature is so large that the error becomes very large if I. Gupta and J.C.M. Li's method is applied. This is the reason why the authors failed to obtain a reasonable value of  $m^*$  at room temperature in a previous paper. 9 refs.

**084161  $[As(V)As(III)O_6]^{4-}$ : AN UNCOMMON ANION GROUP IN THE CRYSTAL STRUCTURE OF  $K_2Cu_3(As_2O_6)_2$ .** The crystal structure of  $K_2Cu_3(As_2O_6)_2$  was determined from single-crystal X-ray data by a direct method strategy and Fourier summations. The structure consists of  $As(V)O_4$  tetrahedra and  $As(III)O_3$  pyramids linked by a common O corner atom to  $[As(V)As(III)O_6]^{4-}$  groups with symmetry  $m$ . The  $As_2O_6$  groups and the Cu coordination polyhedra are linked to sheets parallel to (001). These sheets are connected by the K atoms. Single crystals of  $K_2Cu_3(As_2O_6)_2$  suitable for X-ray work were synthesized under hydrothermal conditions. (Edited author abstract) 21 refs.

Effenberg, H. (Univ Wien, Vienna, Aust); Pertlik, F. *J Solid State Chem* v 70 n 2 Oct 1987 p 219-224.

**084162 CRYSTAL STRUCTURE AND ELECTRICAL PROPERTIES OF  $K_3Bi_2(VO_4)_3$ , A NEW POTASSIUM BISMUTH VANADATE.** The crystal structure was determined from single-crystal intensity data obtained by means of an automated four-circle diffractometer and refined to the conventional values  $R = 0.050$  and  $R_w = 0.059$  for 1498 observed reflections. The structure is characterized by a three-dimensional network of  $Bi_2O_{10}$  units and  $VO_4$  tetrahedra. A  $Bi_2O_{10}$  unit is formed by two  $BiO_6$  octahedra sharing an edge.  $K^+$  ions occupy three

different crystallographic sites. One of them has a high thermal vibration which could reflect ionic mobility. The ionic conductivity highly increases at 790 K. DSC measurements show a reversible transition at this temperature. One K atom, and only one, can be substituted by one Na atom to give  $NaK_2Bi_2(VO_4)_3$ ; this substitution improves the conductivity. (Edited author abstract) 9 refs.

**084164 POTASSIUM MONOPHOSPHATE TUNGSTEN BRONZES WITH HEXAGONAL TUNNELS,  $K_x(PO_3)_4(WO_3)_{2m}$ : X-RAY DIFFRACTION AND NREM STUDY.** The series  $K_x(PO_3)_4(WO_3)_{2m}$  has been investigated by X-ray diffraction and electron microscopy. Five compositions have been isolated as pure phases for  $x = 2$  and  $m = 4, 6, 7, 8$ , and 10. These bronzes are built up from  $WO_3$  slabs connected through  $PO_4$  groups forming hexagonal tunnels. High-resolution lattice images allow a correlation between the image contrast and the structure to be established. Three groups of defects are observed in the crystals which deal with (i) the distribution of the phosphate planes with respect to the  $ReO_3$ -type slabs, (ii) the distribution of the  $K^+$  ions in the tunnels, and (iii) the uneven arrangements of the phosphate planes. (Edited author abstract) 23 refs.

Domenges, B. (Laboratoire de Cristallographie et Sciences des Matériaux, Caen, Fr); Hervieu, M.; Raveau, B.; O'Keeffe, M. *J Solid State Chem* v 72 n 2 Feb 1988 p 155-172.

**084165 SUBSTRUCTURES DE TYPE FLUORINE OBSERVÉS DANS LES SYSTÈMES  $KF-LnF_3$  ( $Ln = Pr...Er$ ). [Observed Fluorine Structures in the Systems  $KF-LnF_3$  ( $Ln = Pr...Er$ ).** Phases having fluoride-related superstructures are determined in the system  $K_{0.5-x}Ln_{0.5+x}F_{2+2x}$ . The composition range in which they are observed has been studied by X-ray and electron diffraction at high resolution. An incommensurate modulated structure appears, with a wave vector  $q = yb_0^*$ . This incommensurate structure is limited by two commensurate phases. (Edited author abstract) In French. 4 refs.

Le Fur, Y. (CNRS, Grenoble, Fr); Aleonard, S.; Perroux, M.; Gorius, M.F.; Roux, M.T. *J Solid State Chem* v 72 n 2 Feb 1988 p 173-180.

**084166 COPPER (III) PERIODATE PEROXO COMPLEX:  $K_4H_4Cu(IO_6)_2O_2 \cdot 6H_2O$ .** The chemical preparation and crystal structure of the trivalent copper salt  $K_4H_4Cu(IO_6)_2O_2 \cdot 6H_2O$  are described. Crystals are monoclinic. The structure is refined until  $R = 0.038$  for 2223 reflections. Isolated  $Cu(IO_6)_2^{7-}$  units and  $O_2^{2-}$  superoxide groups occur. In the  $Cu(IO_6)_2^{7-}$  unit, the trivalent copper ion is surrounded by four oxygen atoms in a rectangular configuration. (Edited author abstract) 13 refs.

## Synthesis

**084169 SYNTHESIS AND CRYSTAL STRUCTURE OF  $\text{KMn}_2\text{O}(\text{PO}_4)(\text{HPO}_4)$ .**  $\text{KMn}_2\text{O}(\text{PO}_4)(\text{HPO}_4)$  crystallizes in the monoclinic space group  $\text{P2}_1/\text{m}$ , with  $a = 6.226(1)$ ,  $b = 6.890(2)$ ,  $c = 8.809(1)$  Angstrom, and  $\beta = 107.67(1)^\circ$ . For  $Z = 2$  the calculated density is  $3.282 \text{ g cm}^{-3}$ . Crystals were obtained hydrothermally, from a mixture of  $\text{Mn}_2\text{O}_3$ ,  $\text{KH}_2\text{PO}_4$ , and  $\text{H}_2\text{O}$ , by slow cooling from 673 K under an external nitrogen pressure of 3 kbar. The structure is composed of zigzag chains of edge sharing  $\text{MnO}_6$  octahedra linked together by  $\text{PO}_4$  tetrahedra to form sheets parallel to the  $bc$  plane. These sheets are linked to adjacent ones via additional  $\text{PO}_4$  tetrahedra and hydrogen bonds. The resulting framework encloses channels running parallel to the  $[011]$  direction in which the potassium resides. (Edited author abstract) 12 refs.

**084170 SYNTHESSES, ETUDE STRUCTURALE PAR DIFFRACTION X, SPECTROSCOPIES INFRAROUGE ET MOESSBAUER DE  $\text{K}_2\text{SeO}_4 \cdot \text{SbF}_3 \cdot \frac{1}{2} \text{H}_2\text{O}$ .** [Synthesis, Structural Study by X-Ray Diffraction, Infrared and Mossbauer Spectroscopy of  $\text{K}_2\text{SeO}_4 \cdot \text{SbF}_3 \cdot \frac{1}{2} \text{H}_2\text{O}$ ]. The X-ray crystal structure of  $\text{K}_2\text{SeO}_4 \cdot \text{SbF}_3 \cdot \frac{1}{2} \text{H}_2\text{O}$  is reported. It crystallizes in the orthorhombic space group  $\text{Pnma}$  with  $a = 10.560(5)$ ,  $b = 12.803(4)$ ,  $c = 11.806(4)$  Angstrom,  $Z = 8$ , and a final  $R = 0.034$ . The antimony environment is that of a distorted dodecahedron  $\text{SbF}_3\text{O}_4\text{E}$  where E represents the nonbonding electron pair of  $\text{Sb}^{III}$ . For  $\text{K}_2\text{SeO}_4 \cdot \text{SbF}_3 \cdot \frac{1}{2} \text{H}_2\text{O}$ , infrared and antimony-121 Mossbauer spectra have been recorded; the data of the title compound and of other complexes are interpreted in terms of  $\text{SbX}_3\text{E}$  and  $\text{SbFX}_6\text{E}$  distorted environments. In all case the nonbonding electron pair is stereochemically active. (Author abstract). 18 refs. In French.

## Testing

**084171 SYSTEM  $\text{K}_2\text{SO}_4\text{-(NH}_4)_2\text{SO}_4\text{-DMF-H}_2\text{O}$  AT  $20^\circ$ .** Studies are now in progress for finding new salting-out

agents for the production of chlorine-free sulfate-containing salts with potassium chloride. We tested dimethylformamide (DMF) for this purpose in conversion of potassium chloride and ammonium sulfate. For scientific validation of the possibility of using DMF in conversion of  $\text{KCl}$  and  $(\text{NH}_4)_2\text{SO}_4$  we studied salt solubilities in the systems  $\text{K}_2\text{SO}_4\text{-(NH}_4)_2\text{SO}_4\text{-H}_2\text{O}$  and  $\text{K}_2\text{SO}_4\text{-(NH}_4)_2\text{SO}_4\text{-DMF-H}_2\text{O}$  at  $20^\circ$ , which corresponds to the optimal conditions for this reaction. There is no information in the literature on the solubilities of these salts at  $20^\circ$  in presence of DMF. Experimental evidence shows that the solubility isotherms of potassium and ammonium sulfates are represented by a single solubility curve, corresponding to formation of continuous solid solutions of the  $(\text{K}, \text{NH}_4)_2\text{SO}_4$  type. In the system  $\text{K}_2\text{SO}_4\text{-(NH}_4)_2\text{SO}_4\text{-DMF-H}_2\text{O}$  containing 20% DMF the solid-solution field increases while the field of unsaturated solutions decreases, indicating salting-out of solid solutions from the liquid phase by DMF. 6 refs.

## Thermal Effects

**084172 TEMPERATURE OF THE TETRAFLUOROALUMINATES  $\text{K}_{1-x}\text{Rb}_x\text{AlF}_6$  EVOLUTION OF THE SHEAR STRUCTURAL PHASE TRANSITION.** By DSC, X-ray diffraction and neutron powder diffraction the temperature behavior of the  $\text{K}_{1-x}\text{Rb}_x\text{AlF}_6$  compounds is investigated in the concentration range  $x = 0$  to  $x = 0.10$ . For large crystals it is shown that if  $x$  is greater than 0.02 the shear transformation of pure  $\text{KAlF}_6$  splits into two structural phase transitions. The structures are determined by neutron powder profile refinement and the space groups  $\text{P4}/\text{mbm}$ ,  $\text{P2}_1/\text{m}$  and  $\text{P2}_1/\text{m}$  are attributed to the three successive phases. The high and low temperature phases are the same as in pure  $\text{KAlF}_6$ . It is shown that the temperature of the transition leading to the low temperature phase is sample size dependent. (Edited author abstract) 11 refs.

Thermodynamics See LEAD COMPOUNDS—Thermodynamics.

## Thin Films

**084173 NOISE AND SHAPIRO STEP INTERFERENCE IN THE CHARGE-DENSITY-WAVE CONDUCTOR  $\text{K}_{0.3}\text{MoO}_3$ .** Extremely thin (transverse dimensions about  $0.2 \mu\text{m}$ ) samples of the charge density wave (CDW) conductor  $\text{K}_{0.3}\text{MoO}_3$  are found to display unusually coherent narrow-band noise spectra and well defined Shapiro step interference structure. The results suggest an intrinsic pinning potential with periodicity equal to the CDW wavelength. The Shapiro step interference appears to arise from a coupling of the external electric field to the low frequency dielectric relaxation mode rather than to the high frequency pinned phason mode. (Author abstract) 24 refs.

## Vaporization

**084174 MECHANISM AND THERMODYNAMICS OF THE VAPORIZATION OF  $\text{K}_2\text{CrO}_4$ .** The vacuum vaporization behavior of  $\text{K}_2\text{CrO}_4$  was studied over the range 1075-1240 K, which is just below the melting point of the material. Both molecular vaporization of  $\text{K}_2\text{CrO}_4$  and decomposition to  $\text{K(g)}$ ,  $\text{O}_2(\text{g})$ , and  $\text{Cr}_2\text{O}_3(\text{s})$  contribute to the total vaporization flux. Vapor composition and sublimation thermodynamics were studied by Knudsen cell mass spectrometry, while total vapor pressure and vapor molecular weight were determined by the torsion-effusion method. Composition data inferred

from the mass spectrum, the vapor molecular weight data, and comparison of calculated decomposition pressure with measured total pressure are all in close accord in showing the molecular chromate  $\text{K}_2\text{CrO}_4$  to account for 83% of the total sublimation pressure. (Edited author abstract) 26 refs.

## Viscosity

**084175 VISCOSITY OF POTASSIUM NITRATE + SILVER NITRATE MELT MIXTURES.** The viscosity of  $\text{KNO}_3 + \text{AgNO}_3$  melt mixtures has been determined in the range  $0.25 \leq x(\text{AgNO}_3) \leq 1.460$  K to 610 K. The viscosity of pure  $\text{KNO}_3$  was measured over the temperature span 620 K to 720 K. An oscillating-cylinder viscometer was used. This method is absolute and requires no calibration against reference liquids. The viscosities in units of MPa s conform to the expanded Arrhenius type equation with 0.04 to 0.31% standard deviations in the fit. (Edited author abstract) 14 refs.

X-ray Analysis See Also CEMENT—Alumina.

**084176 TEMPERATURE VARIATION OF DEBYE-WALLER FACTOR OF  $\text{KNO}_3$ .** In the present work measurements of X-ray diffracted intensities at various temperatures were carried out with the object of extracting the overall X-ray Debye-Waller factor (B) for  $\text{KNO}_3$ , in order to study the variation of the overall Debye-Waller factor of  $\text{KNO}_3$  below and above the phase transitions. It is clear from the values of  $\theta_M$  that it remains practically constant. On the other hand, the Debye-Waller factor increases with increasing temperature below the phase transition and decreases above the phase transition. This is not surprising because the phase change is associated with appreciable variations in the atomic parameters and electron distributions and these, in turn, have significant effect on the mean atomic displacements. 11 refs.

**084177 ON THE DISTORTION WAVE VECTOR IN THE BLUE BRONZES.** We present X-ray measurements of the distortion wave numbers and their temperature evolution in the blue bronzes  $\text{K}_{0.3}\text{MoO}_3$  and  $\text{K}_{0.28}\text{MoO}_3$ , the stoichiometry  $\text{K}/\text{Mo}$  of which has been established using structural refinements as well as an electron probe microanalysis. The results show an independence of the wave number upon the alkaline concentration. We find that both samples have the same wave vector  $Q \approx (0, 0.75, 1/2)$  at low temperature, whereas in the quasi-one-dimensional band filling consideration and a Peierls scenario, the wave vector, for a  $\text{K}_{0.28}\text{MoO}_3$  stoichiometry, is expected to be  $Q = (0, 0.70, 1/2)$ . The results are discussed in terms of either an additional non-stoichiometry or possible warped Fermi surface and bare phonon dispersion effects. (Author abstract) 13 refs.

## POTASSIUM RUBIDIUM ALLOYS

### Electric Conductivity

**084178 VERY-LOW-TEMPERATURE RESISTIVITY ANOMALY OBSERVED FOR POTASSIUM-RUBIDIUM ALLOYS: EFFECT OF A SHORT ELECTRON MEAN FREE PATH.** The anomalous very-low-temperature resistivity data reported recently for concentrated potassium rubidium alloys have been explained by applying the Pippard ineffectiveness condition

to inelastic electron-impurity scattering, thus taking into account the fact that the electron mean free path is finite. A discussion is presented of the Pippard condition, its successes and limitations, and further experiments are suggested for clarifying the role of the Pippard condition in modifying the low-temperature resistivity of concentrated crystalline alloys. (Author abstract) 21 refs.

#### Automatic Testing

**084180 AUTOMATIC TEST INSTRUMENT FOR PRECISE WIRE-WOUND POTENTIOMETER.** Linearity, function conformance, and short circuits between turns have direct effect on the applications of the potentiometer used in automatic control and instrument systems. So the parameters of potentiometers should be precisely measured in production processing. But in traditional method, the accuracy and efficiency are not high. At the same time, some parameters, as specified in IEC standard, can not be tested. According to the specification of IEC, some mathematical models are applied to the linearity of potentiometers in this paper, in which the principles and applied methods of an automatic test equipment for potentiometers are described. **084191 EFFECT OF SHOCK AND ELASTIC WAVES ON DYNAMIC COMPACTION PROCESS OF TWO-LAYER POWDER MEDIA.** The dynamic compaction processes of copper powder which was filled in two layers into a die and subjected to solid punch impact were investigated experimentally in order to assess the effect of different initial density distributions of the powder on the compaction process. The compaction experiments were performed for two situations for layer arrangement: in the first situation the upper layer had a lower uniform initial density distribution than the lower layer and in the second this order was reversed. The processes were photographed for the two situations of layer arrangement using a high speed camera in order to analyze the movement of powder medium and punch, the propagation of shock and elastic waves in the powder medium and density distributions. The pressure on the plug supporting the medium in the die was also measured so that the analysis of the photograph would be facilitated. (Edited author abstract) 13 refs.

**084192 EXPERIMENTAL VERIFICATION OF THE SIMILARITY OF DYNAMIC COMPACTION PROCESSES OF A COPPER POWDER MEDIUM IN DIES OF ELEMENTARY SHAPES.** The similarity of dynamic compaction processes was investigated theoretically and predicted in our previous report, where powder media in a die were assumed to be of a simple type, and the punch and plug to be rigid bodies. The predictions were based on a set of one-dimensional equations and a set of nondimensionalized one-dimensional equations. The objective of this study is to examine the similarity experimentally and to present the results of compaction experiments in order to verify the existence predicted. The experiments were carried out on a copper powder medium in dies having inner cross-section in elementary shapes such as circle, square and triangle. The pressure of the medium at a point contacting the end of the plug, the density distribution and mean density of the green compacts were measured in the experiment. (Edited author abstract) 7 refs.

Miyagi, Kiyohiro (Univ of Ryukyus, Okinawa, Jpn); Sano, Yukio; Hayashi, Takuo. *J Eng Mater Technol Trans ASME* v 109 n 4 Oct 1987 p 306-313.

**084193 ANALYSIS METHOD FOR THE DYNAMIC COMPACTION PROCESSES OF POWER MEDIA WITHIN A DIE.** A method of analysis for the multishock compaction process of die-contained power media with a plug at one end and an impacting punch at the other end is presented. In the method assumptions are made that the media are of a simple rigid-plastic type, and compressed only at the fronts of the shock waves passing through, and furthermore the punch and plug are rigid bodies. Based on the assumptions, particle velocities of elements between the punch surface and a shock wave front are the same and equal to the punch velocity, while velocities of elements between the front and the plug surface are equal to a velocity of the plug surface, i.e., zero. Therefore, it is possible to use jump conditions at the front and equations of motion for the punch and medium moving with the same velocity as it, instead of partial differential equations, i.e., conservation equations which were used in other methods. (Edited author abstract) 12 refs.

**Computer Integrated Manufacturing** See Also PRESSES—Automation.

**084194 CALCULATION OF PM TOOLS FOR PRESSING AND SIZING.** PM moulding tools are calculated by using two parameters. The first is based on the assumption that the elastic swelling from the dimensions of a rigid dies is horizontally isotropic. The second is the pressure on the die which causes its deformation. M.A. Eudier of Alliage Frittes Metafram, in Paris, France, Describes in this paper the development of a computer program which takes into consideration these calculations in the design of PM moulding tools. For the sizing tools the principles are identical but new parameters are added. They are the positive or negative clearances, between the part and the die and between the part and the core-rod. Interesting results have especially been obtained for gears. It has been possible to show that the calculation is roughly ten times more precise than that produced practically. (Author abstract) 1 ref.

**Deformation** See Also POWDER METALLURGY—Aluminum Silicon Nickel Alloys.

**084196 VARIATION OF THE DEFORMATION CHARACTERISTICS OF POROUS BLANKS FROM TITANIUM, COPPER, AND ALUMINUM POWDERS.** Experiments were carried out under isothermal conditions on sintered and unsintered blanks with relative densities of 70-100% pressed from the following powders PTES-1 (titanium), PTEK-1 (titanium), screened TG-TV sponge titanium, PMS-1 (copper), and PA-2 (aluminum). The study was based on compressive testing which was performed under standard forging presses at various speeds. The variations of Poisson's ratio and modulus of elasticity with density were determined at various temperatures from 400-100°C. The method of testing in compression in a stressed and strained mode corresponds to the first stage (upsetting) of forging and extrusion processes. It enables stable test results to be obtained in the whole density range and characterizes the properties of metals under conditions of densification. 1 ref.

## Density Measurement

**084197 ANWENDUNG DER DICHTMESSUNG ZUR POROSITAETSCHARAKTERISIERUNG PULVERMETALLURGISCHE HERGESTELLTER TEILE.** [Application of Density Measurement for Characterization of Porosity of Powder Metal Products]. This paper is concerned with problems involved in density measurements with a view to porosity characterization. Due to the rapid increase of the measurement error with the decrease

of specimen volumes, a minimum specimen volume of approx. 0.5 cm<sup>3</sup> has to be strictly observed. This in turn strongly hampers the application of density measurement in order to characterize local density differences in powder-metal products. A procedure which allows a safe definition of such density differences is described. (Edited author abstract) In German. 6 refs.

**084199 FREQUENCY RELATIONSHIP OF THE ELECTRICAL RESISTANCE OF CERMET FILMS BASED ON THE HEXABORIDES OF RARE-EARTH ELEMENTS.** In this work an investigation was made of the conductivity of cermet films with an alternating current in the 100 kHz-300 MHz range. The conductivity of the film depends on the configuration of the specimens and on the structure and composition of the films. The relationship of conductivity to specimen configuration may be explained by the influence of the distributed capacitances between the electrodes and near-electrode areas of the resistive layer. A new interpretation of the experimental data is proposed. In high-resistance films, breaks in the conducting chains are shunted at high frequencies by intergranular capacitances which leads to an increase in conductivity. The theoretical frequency relationship of conductivity calculated with the use of the theory of percolation agrees with the experimental data. 6 refs.

**084200 SOME FEATURES OF INVESTIGATION OF LARGE PLASTIC STRAINS IN THE EXTRUSION OF SINTERED MATERIALS BY THE FINITE-ELEMENTS METHOD.** In powder metallurgy, extrusion of sintered blanks is employed as a means of obtaining materials possessing good physicochemical characteristics. At the large plastic strains characteristic of extrusion processes it is necessary to determine the distribution of the pressing and find zones of porosities and sites of nonporous structure and cracks. To check the results of theoretical investigations of extrusion through a flat and a conical die, hardness tests were carried out on deformed porous specimens of Pzh4M2 fine reduced iron powder. 5 refs.

**084201 THEORETICAL INVESTIGATION OF THE PROCESS OF COLD EXTRUSION OF RODS FROM UNPLASTICIZED METAL POWDERS. I. DISTRIBUTION OF POROSITY AND STRESSES IN THE CONICAL SEAT OF PLASTIC DEFORMATION.** Existing theoretical solutions of the extrusion problem are applicable mainly to sintered porous metals. The stressed-strained state, variation of porosity in the conical seat of deformation, and the energy and force parameters of the process of cold extrusion of unplasticized powders were investigated. Methods of solution based on continual representations of a compressible powder medium were used. 12 refs.

**084202 THEORETICAL INVESTIGATION OF THE PROCESS OF COLD EXTRUSION OF RODS FROM UNPLASTICIZED METAL POWDERS - III. EXTRUSION PRESSURE.** Rod extrusion pressure determinations were made by solving simultaneously problems on the extrusion of a powder through a conical die and single-ended pressing in its container. An axisymmetric problem is considered on the single-ended pressing of the powder in the container preceding the extrusion stage. The stressed and strained state was determined. The proposed method of calculation makes it possible to determine the extrusion pressure of P/M rods and geometric tool parameters necessary for the production of parts with a given porosity. 9 refs.

## Fabrication

**084203 P/M PLANT AUTOMATION.** The role and importance of plant automation in the production of P/M structural parts are considered, and several examples of implementation in Japan are cited. Six approaches are discussed by which automation can achieve lower production costs: the grouping of P/M parts, making the production system flexible, practicing quality control within the production process, decreasing the idle time of production units, use of work systems in which operators perform multiple tasks, and making automation a function of parts quantity and complexity. With a move toward a greater number of part shapes/sizes and smaller part runs in a given plant, flexibility is necessary in the design of automated production systems. It is also likely that each parts producing plant will have to develop its own automated equipment to fit specific requirements. (Author abstract)

**Forging** See Also POWDER METALLURGY—Aluminum Silicon; POWDER METALLURGY—Densification; POWDER METALLURGY—Iron.

**084207 COMPUTER AIDED DESIGN OF PRE-FORMS FOR POWDER METAL FORGING.** A study funded by the National Science Foundation investigated the feasibility of computer aided preform design for powder forging. The project melded a CAD description of part geometry, artificial intelligence programming techniques (AI), and numerical methods of metal working plasticity analysis. Contributions from AI included new methods of internal representation of part geometry and properties, a knowledge base which captured the design logic, and a decision technique that implemented the design logic. In addition to application of AI methods, a major accomplishment was interfacing of a module for mathematical modeling of the deformation pressures required in each region of the part. This module was accessed to aid in decision making during the design phase. This article summarizes the results of the study.

## Friction

**084208 FRICTION MECHANISMS OF ANTI-FRICTION PRODUCTS.** Friction materials made from mixtures of metal and ceramic powders are used in applications where the friction coefficient must be very high, for example in aircraft brakes, brakes on high speed TGV trains and on trains operating in mountain regions. This paper describes work done to study the mechanisms which influence the friction properties of copper-base products containing metallic glasses. The mechanisms proposed are specific to the applications which have been made. There are other ways to transform mechanical energy into heat but SSD and viscous films are among the most simple ones. 3 refs.

**Heat Transfer** See HEAT TRANSFER—Radiation.

**Heat Treatment** See Also POWDER METALLURGY—Iron Graphite; POWDER METALLURGY—Steel; POWDER METALLURGY—Superalloys; STEEL HEAT TREATMENT—Carburizing.

**084209 DEVELOPMENTS IN SINTERING INJECTION MOULDED PM PARTS.** Injection moulding of metal powders holds considerable promise for the development of a new range of highly complex PM compo-

nents. However, one of the drawbacks of the process is that it takes many hours and even days to remove the binder used to assist moulding of parts, thereby adding to production costs. A new, one-step binder removal and sinter process has been developed based upon vacuum techniques. Both laboratory size and production size equipment has been developed in parallel. The result is a much shorter single cycle processing time for a range of parts, as well as good control of carbon levels. As the process, materials and equipment are further developed, a much wider range of cost-effective parts can be expected to appear in the marketplace.

Kennedy, Sheldon W. (Vacuum Industries Inc, Somerville, MA, USA). *Met Powder Rep* v 42 n 9 Sep 1987 p 609-611.

**084210 PREDICTING CASE DEPTHS FOR VACUUM CARBURIZING.** Curves for estimating effective case depth relative to processing variables and part density simplify procedure. Surface-hardening steel powder-metal (PM) parts has long posed problems because the sintered parts are generally porous and, therefore, not homogeneous. Carbon potential, the driving force in conventional atmosphere carburizing, depends on balancing atmosphere constituents under non-equilibrium conditions. If the constituents - carbon monoxide, carbon dioxide, hydrogen, nitrogen, water vapor, oxygen, and, if carbonitriding, ammonia - are not properly controlled, carburizing/decarburizing and reducing/oxidizing reactions can slow the rate of carbon absorption. Care is also required to minimize surface dealloying.

Vaccari, John A. (American Machinist & Automated Manufacturing, New York, NY, USA). *Am Mach Autom Manuf* v 131 n 9 Sep 1987 p 160-161.

**084211 ION NITRIDING REDUCES DISTORTION, IMPARTS DISTINCT CASE DEPTHS.** Having major advantages over conventional methods, ion nitriding may be adopted by a major user of PM parts. Rapidly emerging as an effective treatment for altering the surface characteristics of many materials, ion nitriding may soon find a home at Pitney Bowes (Stamford, Conn), long a major producer and user of PM parts. Because of its advantages over conventional carbonitriding and vacuum carbonitriding, it is being considered for surface-hardening cams, gears, pulleys, and other steel PM parts as well as for punching and stamping dies.

Anon. *Am Mach Autom Manuf* v 131 n 9 Sep 1987 p 161-162.

**084212 HEAT TREATMENT OF SINTERED STEELS MADE FROM A PARTIALLY PREALLOYED IRON POWDER.** Compacts of steels containing 1.75% nickel, 1.5% copper, 0.5% molybdenum and 0%, 0.3% or 0.6% carbon with about 6% or 15% porosity were sintered at 1150°C for 1 h. Subsequently they were austenitized at 850°C for 0.5 h, quenched in either oil or water and tempered at temperatures in the range 200°C...700°C for 1 h. The carbon-containing steels responded to the heat treatments in a similar manner to wrought steels, and developed tensile properties that were markedly superior to those of the same steels that were in the sintered and fairly slowly cooled condition. The strengths of the steels that had been tempered at temperatures up to about 500°C decreased only slowly with increase in tempering temperature, possibly owing to the effect of the copper in the steels. Carbon-free steels responded to the heat treatment in a different manner, undergoing precipitation hardening in the temperature range 400 to about 550°C, brought about by the precipitation of a copper-rich phase. Optimum strengthening occurred on tempering at about 500°C. (Edited author abstract) 8 refs.

## Heating

**084213 MODELING THE TEMPERATURE FIELD IN A POWDER MATERIAL SUBJECTED TO DI-**

**RECT ELECTRIC HEATING.** In order to reveal the effect of the temperature gradient in the sintering zone, a study was made of the process of self-propagating high temperature synthesis (SHS) of a powder mixture initiated by direct electric heating. Modeling the temperature field in the SHS or sintering of a powder mixture by the direct passage of a current makes it possible to determine optimum conditions of production of hard-metal materials. These processes are characterized by a multifactorial dependence on starting conditions and design features of the set-up. 5 refs.

**084215 PRESENT STATUS OF PM INJECTION MOULDING (MIM) - AN OVERVIEW.** The current technologies for metal injection moulding (MIM), including Wiech, Rivers, and others are reviewed. The factors affecting the growth of the industry are summarized and compared with the impeding factors. This leads to estimates of the cost of making MIM parts, how they compare with investment castings, and a forecast for future market growth. The present markets, shipments, tooling, technology, and history of the 29 active MIM producers in North America and Europe are reviewed by company. A table contains mechanical property data for MIM materials. Work under way at various research institutions and efforts at standardization are described. 51 refs.

Pease, Leander F. III (Powder-Tech Associates Inc, North Andover, MA, USA). *Met Powder Rep* v 43 n 4 Apr 1988 p 242-243, 245-247, 249-254.

**084216 PRODUCTION AND EVALUATION OF PM INJECTION MOULDING FEEDSTOCKS.** The authors investigated several types of polymer/stainless steel powder feedstocks for powder injection moulding with respect to preparation and evaluation techniques. Categories of polymer binders examined include waxes, plastics and wax/plastic combinations. Oil smear tests were performed to determine the maximum powder loading. Preparation techniques for each system varied with the type of binder. Waxes could be easily melted and the powder added directly, whereas with plastics or wax/plastic combinations a solvent was used to dissolve the binder before adding the powder. Evaluation of the feedstock density was performed to determine the reproducibility of the composition of the blend. Specific gravity was determined. 8 refs.

**084217 ADVANCED POWDER PROCESSING RESEARCH FOCUSES ON INJECTION MOULDING.** An industrially sponsored research programme entitled 'Advanced Powder Processing' has been initiated at

Rensselaer Polytechnic Institute in Troy, New York. The research focus is on powder injection moulding. The article reviews some of the research aspects of the programme and its objectives in producing components with complex geometries, close tolerances, unique microstructures and improved properties.

Anon. *Met Powder Rep* v 43 n 4 Apr 1988 p 262-263.

**084218 METAL INJECTION MOULDING, A NEW FABRICATION TECHNIQUE FOR SINTERED PARTS OF INTRICATE GEOMETRY.** Powder metallurgical (PM) injection molding is a new net-shape forming process for small parts of intricate geometry, to be fabricated in large production runs. It is similar to plastic injection molding, using a plastic coated metal powder as feedstock. Removing the plastic after injection molding and subsequent sintering the parts to high density results in a family of new PM-products. This article describes in detail the process, presents examples illustrating the potential of this technique in various industrial sectors, and discusses its economy.

## Lubricants

**084219 NEW METHOD OF DETERMINATION OF THE OIL CONTENT IN POROUS POWDER METALLURGY PARTS.** The authors have developed a method of determination of the quantity of oil in porous powder metallurgy parts. The basis is the phenomenon of thermal destruction of the molecules of a lubricant material. As the result of the action of high temperature the molecules of a chain-type oil decompose into shorter portions. As the result of their shorter length and lower molecular weight they acquire in vacuum an increased volatility and are almost completely removed from the pores of the powder metallurgy part. 4 refs.

**Machining** See Also POWDER METALLURGY—Densification; POWDER METALLURGY—Iron; POWDER METALLURGY—Steel.

**084220 MACHINABILITY OF POWDER METALLURGY MATERIALS.** This paper reviews the prior research performed on the machinability of powder metallurgy (P/M) materials and describes recent related studies by the authors. Most of the P/M machining literature has been focused on the influence of additives on machinability. Little effort has been expended on studying the effects of porosity, machining parameters, cutting tool parameters and processing variables on the machinability of P/M parts and materials. This paper describes these effects based on tests using 304L stainless steel P/M materials. The poor machinability of these materials is related to the presence of porosity which affects their mechanical and physical properties. (Author abstract) 44 refs.

Agapiou, John S. (GM Technical Cent, Warren, MI, USA); DeVries, Marvin F. *Int J Powder Metall (Princeton NJ)* v 24 n 1 Jan 1988 p 47-57.

**084221 DRILLED HOLE QUALITY ASSESSMENT IN FERROUS PM COMPONENTS USING SURFACE INTEGRITY TECHNIQUES.** It is suggested that undue emphasis has been placed on tool wear and that the effects of machining on component integrity have not been fully appreciated. Surface integrity can be a more reliable means of assessing the geometric, topographical, and metallurgical characteristics of the machined component and of the machining operation as a whole. The mechanisms involved in drilling a PM product are discussed and it is suggested that hole quality can be linked to other forces generated while cutting and to the vibration that attends machining. Recommendations are made as to the best approach in alleviating these problems with regard to control over sintering conditions and drill shape/geometry. The powders used were Hoganas

ASC100.29 atomised powder (straight iron), Hoganas SNC100.24 sponge iron powder (sulphurised) and Mannesman Demag Fe-Ni-Mo atomised prealloyed powder. (Edited author abstract). 9 Refs.

**084222 TOWER-BUFFER: A NEW CONCEPT TO INCREASE PRODUCTIVITY IN P/M PARTS MANUFACTURING.** A description is given of a tower buffer system for the automatic accumulation of output from compacting presses, automatic loading and retrieval from sintering furnaces, sizing and calibration, cleaning/washing, and packing and shipping. Experience with the concept in Europe suggests that improved productivity can be achieved through automation in handling. This results in improved plant integration, operational flexibility, and increased utilization of equipment. (Edited author abstract)

Miller, Jerry H. (North American Automation, Glen Ellyn, IL, USA). *Int J Powder Metall (Princeton NJ)* v 23 n 2 Apr 1987 p 127-128, 130-131.

**084223 P/M COMPONENT PRODUCTION - EXTENDING SHAPE CAPABILITY.** Inherent limitations of the traditional P/M route have tended to restrict certain types of product applications, but a wide range of developments outlined in this article are addressing and solving the problems. The various developments are categorized as follows: those involving manipulations (often minor) to what remains essentially the standard P/M route; those involving the use of isostatic pressure rather than axial compaction; those involving injection techniques; and those involving standard metal forming operations applied to preforms produced by conventional P/M compaction and sintering.

Whittaker, D. (GKN Technology Ltd, Wolverhampton, Engl). *Metallurgia* v 54 n 11 Nov 1987 p S1-S2, S4.

**084224 P/M INJECTION MOULDING EXTENDS PROCESS VERSATILITY.** One recognized disadvantage of P/M manufacture has been the restriction of design geometries mainly due to limitations inherent in the compaction/pressing stage. This article describes a new 'near-net-shape' forming method for sintered parts with intricate geometry. This process combines the advantages of P/M with those of plastic injection molding (offering great possibilities of design). An additional advantage lies in improved microstructural properties of MIM parts due to various process particularities which increase the total benefit that MIM-parts provide.

Poniatowski (Degussa AG, Hanau, West Ger); Will, G. *Metallurgia* v 54 n 11 Nov 1987 p S18-S19.

**084225 METAL INJECTION MOULDING BOOSTS P/M'S RANGE.** Metal injection molding is an emerging powder metallurgy technique which is applicable to the manufacture of small complex components. This technique, as outlined in this article, has proved to be cost-effective for the production of components which would otherwise have to be made by lost wax casting, machining or fabrication of more than one part. The technology's development has also included the successful manufacture of ceramic components. (Edited author abstract)

## Melting

**084228 MELTING POWDER PARTICLES IN A LOW-PRESSURE PLASMA JET.** A numerical model has been developed to predict the temperature history of metal particles injected in a low-pressure (supersonic) d-c plasma jet. The temperature and velocity fields of the plasmajet are predicted by solving the parabolized compressible Navier-Stokes equations using a spatial marching scheme. Particle trajectories and heat transfer characteristics are calculated using the predicted plasma jet temperature and velocity fields. Correction factors have been introduced to take into account the noncontinuum effects encountered in the low-pressure environment. The plasma jet profiles as well as the particle/plasma interactions under different jet pressure ratios (from underexpanded to overexpanded cases) have been investigated. (Author abstract) 27 refs.

**084230 EFFECT OF 5-20 WT.-% CHROMIUM ADDITION ON THE OXIDATION BEHAVIOUR OF NICKEL-COBALT-THORIUM OXIDE COMPOSITES AND STUDY OF THE OXIDE SCALES.** Ni-Co-ThO<sub>2</sub> composites prepared by a coprecipitation method have been studied under air oxidation conditions between 800 and 1000°C. Thermogravimetry showed slight but continuous oxidation of the material. The effect of 5-20% chromium powder additions to the base powder mixture was studied. The results demonstrated significant decreases in oxidation rate, starting from 10 wt.-% chromium addition while efficient protection was obtained from 15 wt.-% by formation of a Cr<sub>2</sub>O<sub>3</sub> scale. Polarized light microscopy studies, as well as scanning electron microscopy, coupled with x-ray emission microanalysis and x-ray diffraction, enabled qualitative analysis of the different zones distinguished inside the oxide scale. This led to the establishment of an oxidation mechanism related to the chromium content. (Author abstract) 15 refs.

Ghods, M. (Univ Libre de Bruxelles, Brussels, Belg); Beatse, T.; Geuens, C. *React Solids* v 4 n 1-2 Oct 1987 p 41-51.

**084231 HIGH TEMPERATURE OXIDATION AND CRYSTALLOCHEMICAL INTERACTION OF THE Kh18Ni10-SiC-SiO<sub>2</sub>-Al<sub>2</sub>O<sub>3</sub> SYSTEM DURING HEAT TREATMENT.** Methods of structural (x-ray diffraction and electron diffraction), petrography, and x-ray spectrum microanalysis and metallographic examination were used to study the products of interaction in sintering powder mixtures of Kh18Ni10 corrosion-resisting steel, quartz, carborundum and alumina in oxidizing media (air, vacuum 0.013 Pa) in a wide temperature range (1100-1500°C) and holding times (up to 50 h). It is shown that in addition to oxidation of the component of the mixture as a result of diffusion and crystallochemical interaction, spinel phases also form; these phases protect the metallic component of the mixture against complete oxidation, and the method of production of the cermet (cold compacting or hot extrusion) and the form and dimensions of the specimens (cylindrical or flat, thin or thick) exert a strong effect on the phase composition of the final product. (Author abstract) 20 refs.

## Quality Assurance

**084236 COST OF QUALITY.** Over the past decade there has been an increasing emphasis on total quality assurance programs in the U.S. The impetus for this emphasis on quality originated with the automotive industry's response to increased competition from Japanese manufacturers. The Japanese competitive edge was based almost solely on quality. In the early and mid 1980's the push for quality in the powder metal industry came from customers in the form of mandated statistical process control (SPC) programs. The intent of this article is to stress the measuring of quality costs as a tool for evaluating the SPC program. A simple definition of quality costs is all costs relating to or resulting from making defective products. In reality, these are costs of not having quality.

Reliability See AIRCRAFT MATERIALS—Light Metals.

Solidification See Also POWDER METALLURGY—Aluminum.

**084237 DYNAMIC CONSOLIDATION OF RAPIDLY SOLIDIFIED POWDERS.** Rapid solidification processing (RSP) holds promise for producing engineering alloys with refined microstructures, improved chemical homogeneity, extended solute solubility, and possible retention of metastable phases. Dynamic consolidation can be an attractive alternative to conventional methods for temperature-sensitive materials. Some potential advantages are relatively low bulk temperatures; nearly random crystallographic texture in the product; near-neighbor retention during densification, which may allow forming of composites or dispersion-strengthened materials from powders; shock hardening, which may be useful for wear-resistant applications; and the possibility of deformation-induced phase transformations. The article briefly reports on work with Type 304 stainless steel. 2 refs.

## Stresses

**084238 SINTERING STRESS OF HOMOGENEOUS AND HETEROGENEOUS POWDER COMPOSITES.** The thermodynamic meaning of the sintering stress is considered for some simple 2-dimensional porous bodies. The sintering stress acts as an effective mean grain boundary stress and can thus be combined with applied stresses. The sintering stress cannot be described in rigorous thermodynamic terms, especially for heterogeneous composites. Simplifications allow one to assess the effects of some microstructural heterogeneities, including the presence of large pores or dispersed second phases on the sintering stress. (Author abstract) 17 refs.

## Thermal Conductivity

**084239 HEAT CONDUCTIVITY AND THERMAL DIFFUSIVITY OF HARD ALLOYS OF THE TK TYPE AT ELEVATED TEMPERATURES.** Alloys of the tungsten carbide-titanium carbide-cobalt system (TK alloys) are used in production of tools for metalworking. The aim of this work was to determine the thermal diffusivity of T15KX (mass content of cobalt X = 1.5, 6, 10, 15%) and T20KX (X = 4, 6, 12, 15, 20%) alloys with various amounts of the binding phase. Thermal diffusivity was measured in the temperature range 800-1500°K. The differences in the heat conductivity values determined by experiments and calculated on the basis of the measured heat conductivities of the phase components are caused mainly by differences in the composition of the Co phase and the (Ti, W)C phase of real alloys in relation to the model used for the calculations. 7 refs.

## Wear

**084240 WEAR-RESISTANT POWDER MATERIALS WITH INTERMETALLIC PRECIPITATION HARDENING. II. WEAR-RESISTANT POROUS MATERIALS.** The authors obtained an analytical expression determining the dependence of hardness on the porosity and chemical composition for alloys subjected to precipitation hardening and containing various amounts of alloying elements. They investigated the wear resistance

of the alloys under conditions of dry friction ( $P = 150$  N,  $v = 1$  m/sec). With increasing porosity wear increase parabolically, and with increasing content of AE it decreases parabolically. Aging effects were also studied. 8 refs.

Karapetyan, G.Kh. (Erevan Polytechnic Inst, USSR); Akopov, N.L.; Karapetyan, F.Kh.; Manukyan, N.N. *Sov Powder Metall Met Ceram* v 26 n 5 May 1987 p 421-424.

**084241 WEAR RESISTANCE OF PM Fe-Cu-C MATERIALS CONTAINING STEEL-TiC PARTICLES.** Composite materials with an Fe-Cu-C matrix including steel-TiC particles were made by sintering mixtures containing Fe, Cu and graphite powder and steel-TiC particles between 125 and 1000 microns and infiltrating with copper. The abrasion resistance of these composites was studied using the ASTM B611 method. The results show that the addition of steel-TiC particles does not always improve the wear resistance of the Fe-Cu-C matrix and that the maximum improvement in wear resistance was about 25%. The results are compared to results obtained elsewhere on the abrasion resistance of composites made of a PM steel matrix containing WC-Co cermet particles. 3 refs.

Welding See WELDING, GAS—Superalloys.

## Wetting

**084242 DETERMINATION OF THE PORE SIZES OF PERMEABLE METALLIC MATERIALS BY THE LIQUID DISPLACEMENT METHOD.** Contact angles were determined by the sessile drop method and capillary rise method. Contact angle determinations by the capillary rise method were made, on porous specimens from BrOF10-1 bronze, titanium, and Kh18N15 corrosion-resistant steel powders. Measurements made by the sessile drop method established that iron, nickel, the corrosion-resistant steel, copper, bronze, and titanium were wetted completely by acetone, gasoline, and ethanol and partially by distilled water. This result is linked mainly with the free surface energy of the liquids investigated. It is therefore possible to employ these data in pore size determinations by the Barus-Beghold method. Thus, for ethanol with alcohol content not less than 96.2 wt. % and density  $0.807 \text{ g/cm}^3$  at  $t = 20^\circ\text{C}$  and  $P = 0.1 \text{ MPa}$  the surface tension is  $22.8 \text{ mJ/m}^2$ . 14 refs.

**084243 MICROSTRUCTURE AND MECHANICAL PROPERTIES OF THE DISPERSION-HARDENED P/M Al-10% Mn AND Al-10% Mn-2.5% Si ALLOYS.** On two dispersion-hardened P/M Al-alloys, Al-10 wt.% Mn and Al-10 wt.% Mn-2.5 wt.% Si, tensile tests, fatigue tests and fatigue crack propagation tests were performed. The yield stress is mainly controlled by the spacing of the dispersoids, while the true fracture strain is dominated by a certain fraction of the powder particles, in which large precipitates have developed leading to early crack nucleation. When testing in air at  $200^\circ\text{C}$ , a significant ductility reduction in the ternary alloy was observed due to environmental effects. Compared to ingot alloys a good

high-cycle fatigue strength was found. (Edited author abstract) 11 refs.

**084244 RHEOLOGICAL CHARACTERISTICS OF SPHERICAL NICKEL AND STAINLESS STEEL POWDERS.** Published information on the internal and external friction characteristics of spherical metal powders is scant. It was therefore considered of interest to study these characteristics and their variation with fractional composition, using, as examples, atomized nickel (PSN) and 18% Cr-9% Ni stainless steel (PRKh18N9) powders. The method of determining rheological characteristics consists in calculating the force necessary to disintegrate a specimen of a free-flowing material by sliding on a surface, with the simultaneous measurement of the normal compressing load. In this work internal friction testing was preceded by the assembly of the shear unit of the apparatus. A comparative analysis of our results for the various powders from the point of view particle size and morphology indicates that it is the latter factor that exerts a dominant influence on the internal friction of such powders. 6 refs.

Andrievskii, R.A. (Acad of Sciences of the Kirgiz SSR, USSR); Levin, V.P. *Sov Powder Metall Met Ceram* v 26 n 4 Apr 1987 p 299-302.

**084245 FRICTION IN METAL POWDERS.** A technique for measuring interparticle friction has been developed. It employs the concept of sliding a powder monolayer of nearly equal size particles against a flat surface of finite surface roughness and measuring both the normal and shear forces. This paper describes the technique, test equipment, and a novel method for measuring the total number of contact points at the sliding interface. Data measured by this technique show a dependence of the coefficient of friction on both the particle size and normal load and predicts a Hertzian elastic contact at the sliding interface. The data also show that the coefficient of friction of coated powder monolayers depends on lubricant film thickness in a manner similar to that of coated bulk surfaces. (Author abstract) 20 refs.

**084246 POWDER METALLURGY AT THE TURN OF THE NEW CENTURY.** The author examines the powder metallurgy industry in the 21st century. According to this forecasting, by the year 2000 the American P/M parts industry will probably consist of less than its present number of companies. Consolidation will be the key to survival; however, those remaining will be turning over more than double the dollar volume they are today. About 10% of American P/M companies will be foreign-owned or controlled.

Roll, Kempton H. (Metal Powder Industries Federation, Princeton, NJ, USA). *Int J Powder Metall (Princeton NJ)* v 23 n 4 Oct 1987 p 271-276.

**084247 DEVELOPMENTS IN GAS ATOMISATION AND SPRAY DEPOSITION.** The extensive development work on gas atomisation and spray deposition done at MIT and in other laboratories has made possible the production of rapidly solidified powders and compacts of selected sizes for a broad range of alloys, with improved structures and properties. There are however issues that remain to be addressed, such as the fluid dynamics and heat transfer mechanisms during atomisation and deposition, the extent of oxide contamination during deposition and the optimisation of the numerous process parameters in order to get the best material properties at maximal economic efficiency. The present

report summarises the progress made in investigating the above mentioned processing issues over the past years, based on studies undertaken mostly at MIT. 52 refs.

**084253 METAL INJECTION MOLDING EXPERIENCE AT P/M PLANT.** Metal Injection Molding (M.I.M.) is a newly emerging metal working technique which should be especially applicable to small, highly configured, complex metal parts. The process uses very fine, spherical metal particles which are mixed with organic binders and the fluid mixture injected into molds. After setting up in the molds, the part is removed, the binders removed, usually by thermal decomposition, and the resulting metal part is then sintered at high temperature to bond the particles and shrink the structure to near full density. The advantage of the process is its ability to make more complex shapes with the third axis capability than conventional P/M and probably will find its greatest initial market competing with investment castings. The techniques, the properties and microstructures obtained are described.

**084254 MECHANISM OF DEFORMATION AND DISINTEGRATION OF A MOVING DROP.** Now the disintegration of a moving drop in a stationary medium (a liquid) is preceded by its deformation, first into an ellipsoid and then a disk, which finally breaks up in a miniature explosion into smaller droplets. The deformation is accompanied by oscillations about the center of gravity of the drop. The mechanism of disruption is studied numerically. The most probable cause of the explosive character of the break-up of a drop are its resonant vibrations. 15 refs.

**084256 COMPOSITE ENGINEERING BY HOT ISOSTATIC PRESSING.** During the last five years H.I.P. Ltd has recruited a development team to extend the application of HIP processing. Responding to a continued interest in the use of HIP for powder densification and dissimilar material bonding, a separate sister company Infutec Ltd. was formed in April 1987. The current range of activities for both companies are broad but three specific areas of development have emerged and are described.

Anon. *Met Powder Rep* v 43 n 4 Apr 1988 p 270.

**084257 CERAON PROCESS READY TO SHAPE THE FUTURE.** The term 'Ceracon' is an acronym for 'ceramic granular consolidation' and is essentially a quasi-isostatic method of consolidation which has been developed by Ceracon Inc. in Sacramento, Calif. The secret of the process is the pressure transmitting medium (PTM) which transfers the force of the press to the preformed part. The PTM, a graphite or ceramic grain or

a mixture of both, is heated until it glows red at which temperature it exhibits properties similar to those of gases used in a hot isostatic press. By burying the preform or containerised powder in the PTM and applying high pressure at temperature in a conventional hydraulic press, the consolidation cycle at temperature is reduced to only 0.5 to 30 seconds as compared to many hours in HIP and the process allows a predictable shape control over the finished components for the production of near-net shapes. The process can be used to fabricate ceramic superconductors.

**084258 METAL INJECTION MOLDING: THE INCUBATION IS OVER.** Metal injection molding (MIM) was introduced to the P/M community nearly twenty years ago. Since that time, there has been a relatively slow growth in terms of application to parts making. In this article, the author examines the underlying reasons for this disappointing record and cites emerging factors that are expected to turn MIM into a viable component of the P/M industry within five years. (Edited author abstract)

Pease, Leander F. III (Powder-Tech Associates Inc, North Andover, MA, USA). *Int J Powder Metall (Princeton NJ)* v 24 n 2 Apr 1988 p 123-127.

**084259 POWDER METALLURGY INDUSTRY CHALLENGES AND OPPORTUNITIES IN THERMAL PROCESSING AND APPLICATIONS.** The utility of powder metallurgy and needs for thermal processing and production of quality parts for many applications are described. These products comprise different metals formed by different techniques, such as compacting and sintering, hot isostatic pressing, cold isostatic pressing, metal injection molding, spray forming, extrusion, direct powder rolling and consolidation by atmospheric pressure. Technology developments in the automotive industry, a forming and sintering are described. It is shown how P/M parts are replacing conventional metals. Continued growth for the P/M industry is forecast.

Johnson, Peter K. (Powder Metallurgy Equipment Assoc, Princeton, NJ, USA). *Ind Heat* v 55 n 5 May 1988 p 12-13.

**084260 MATERIALS & TECHNOLOGY FOR THE P/M INDUSTRY.** The company Jorn Sandberg Ronne ApS in cooperation with Riso and the Technological Institute Metallurgy has developed a kiln for controlled expulsion of organic additives from ceramic objects. The kiln allows firing in a controlled atmosphere such as atmospheric air, O<sub>2</sub>, and vacuum or expulsion in an inert atmosphere such as argon and N<sub>2</sub>. It is possible to establish a vacuum down to  $-10^{-4}$  bars.

Vago, F. (Teknologisk Inst, Den). *Powder Metall Int* v 20 n 3 May 1988 p 51-52.

**084261 COMPLEX COMPONENTS VIA 'NEW' TECHNIQUES.** Powder metallurgy is not a new process. It owes its origins to the invention, in the early 1900s, of tungsten lamp filaments. But recently there has been a growth in the versatility of the process as a result of new ways of compacting the powder forms. Several of the methods are adaptations of techniques in use with other manufacturing processes. This article outlines some of them.

Kellock, Brian. *Mach Prod Eng* v 146 n 3737 Apr 20 1988 5p.

**084262 VERFAHREN ZUR HERSTELLUNG MIKROKRISTALLINER ODER AMORPHER METALLPULVER.** [Methods of Producing Microcrystalline or Amorphous Metal Powders]. Metal alloys of microcrystalline or amorphous structure are produced by rapid cool-down from the melt. Atomization of metal melts with a high-energy inert gas jet is one of the most economical methods of producing high-quality powders. Using helium as process gas in powder particles of approximately 20 microns in diameter, the microstructure is similar to

that of strip and foil produced on water-cooled copper substrates. Due to their unsuitable shapes, materials produced by melt spinning or melt extraction have to be comminuted to fine metal powder with a uniform particle shape before these materials can be compacted to larger size blanks. The fluidized-bed counterflow jet mill enables brittle, rapidly chilled metal alloys to be optimally processed to a powder with narrow particle size distribution and high purity. (Author abstract) In German. 24 refs.

Joensson, S. (Leybold AG, Hanau, West Ger); Hohmann, M. *Metal* v 42 n 5 May 1988 p 475-480.

**084263 EXAMINATION OF PREGREEN SPECIMEN PROCESS.** The isostatic powder process used at present is based on a procedure in which an elastic (reusable) or a plastic (disposable) mould is filled with powder, possibly with a few per cent of binder and/or lubricant added. The mould is closed and its contents pressed isostatically into green specimens. The pregreen specimen process combines the core making process used in the foundry industry with the conventional isostatic powder process. Powder specimens are produced in a pregreen specimen mould (core box). Experiments were carried out to determine the most suitable binder for the pregreen specimen process. The following were included: phenolic resin + polyisocyanate + triethylamine (cold box); sodium silicate +  $\text{CO}_2$  wax; and water (ice).

Huusmann, O. (Technological Inst of Copenhagen, Copenhagen, Den). *Powder Metall* v 31 n 2 1988 p 90-93.

**084264 ECONOMIC EVALUATION OF PREGREEN SPECIMEN PROCESS.** The pregreen specimen process has the potential to replace casting in certain instances and could also be useful in new areas of production. An economic comparison with the sand mould casting process is presented. Economically the process is comparable with sand casting. The cost considerations were based on production of pulleys in gray iron.

Kraemer, O. (Technological Inst of Copenhagen, Copenhagen, Den). *Powder Metall* v 31 n 2 1988 p 93-95.

**084265 POWDER METALLURGY.** This conference proceedings contains 13 papers covering the following topics: high performance materials made by powder metallurgy; tungsten carbide-cobalt powders recycled by the zinc process; recent developments in new ceramic materials; production of water- and gas-atomized powders; purification of metal powders; ultrasonic gas atomization; use of tin and cobalt as alloying elements in powder metallurgy; metal injection molding; fabrication of sintered parts of intricate geometry; aluminum powder metallurgy; superconducting materials from niobium-titanium powders; and current lead powder applications. All papers are abstracted and indexed separately. Technical and professional papers from this conference are indexed and abstracted with the conference code no. 10639 in the Ei Engineering Meetings (TM) database produced by Engineering Information, Inc.

Anon (Benelux Metallurgie). *ATB Metall* v 27 n 2-3 1987. *Powder Metall*, Brussels, Belg, May 13-14 1987 p 42-121.

**084266 ON SOME PROPERTIES OF WC-Co POWDERS RECYCLED BY THE ZINC PROCESS.** This article discusses experimental results of work in progress on the properties of cemented carbides sintered from powders recycled by the zinc process. It is shown that the use of large amounts of powders recycled by the zinc process in the preparation of sintered material do not affect the mechanical properties (bending and compressive strength) at all for a 50% recycled/50% virgin blend material, and has small effects in the case of 100% recycled parts. On the other hand, the recycled containing samples have a better wear-shock resistance in simulated mining drill conditions. The differences in properties are due to structural effects such as porosities present and mean grain size of the carbides. 3 refs.

**084271 MICROSTRUCTURE AND BONDING OF**

**DYNAMICALLY CONSOLIDATED ALUMINUM AND Al-1.4Co POWDERS.** The mechanism of interparticle bonding and the extent of thermal modification of the microstructure are examined for aluminum and Al-1.4Co powders (where the composition is in approximate weight percent) consolidated at ambient temperatures and  $-50^\circ\text{C}$  using explosives. Dynamically consolidated material with substantial tensile strength is obtained without significantly altering the fine-precipitate microstructure in the Al-1.4Co. The primary bonding mechanism is localized interparticle melting associated with regions of particle extrusion and extensive plastic flow. Defect substructures show extensive recovery in the as-consolidated material resulting directly from the consolidation process rather than from post-consolidation annealing from heat retained in the fixtures. (Author abstract) 21 refs.

Wright, R.N. (Idaho Natl Engineering Lab, Idaho Falls, ID, USA); Doyle, T.E.; Flinn, J.E.; Korth, G.E. *Mater Sci Eng* v 94 Oct 1987 p 225-231.

**084272 COLD FORGING OF METAL POWDER PREFORMS.** This paper reviews the state of the art of cold forming porous preforms into net or near-net shapes for structural applications. Materials discussed include ferrous and aluminum powders. Processes include both bulk and localized cold forming. Analysis of densification and deformation for cold forming of axisymmetric cup shapes, hubs and flanges is presented. Empirically based relationships concerning proper preform design are extended to more complex shapes. (Author abstract) 8 refs.

**084273 WELDABLE RAPIDLY SOLIDIFIED ALUMINUM ALLOY FOR MARINE APPLICATIONS.** A program was initiated to develop weldable rapidly solidified aluminum alloys and associated fusion and solid state joining methods for marine applications. A set of goal properties for this program was developed. Emphasis was placed on identifying alloy compositions and welding techniques which have high potential to meet the desired strength, ductility, and weldability goals. This paper details the results for a promising RSP Mg-Cr aluminum alloy. (Author abstract) 8 refs.

**084274 RAPIDLY SOLIDIFIED ALUMINUM ALLOYS: A MARKET ASSESSMENT.** A survey of the markets for rapidly solidified, high strength aluminum alloys has been made on the basis of currently available technologies. This survey includes an assessment of potentially new developments. Advanced powder metallurgy technologies possess a visible market potential primarily in applications requiring high-strength, heat-treatable alloys of modified 7075 composition (currently alloys 7090 and 7091) and lithium bearing 2XXX series. (Author abstract) 12 refs.

Lavernia, Enrique J. (MIT, Cambridge, MA, USA); Poggiali, Barbara; Servi, Italo S.; Clark, Joel P.; Katrak, Firoze E.; Grant, Nicholas J. *Int J Powder Metall (Princeton NJ)* v 23 n 1 Jan 1987 p 55-60.

**084275 HIGH STRENGTH ALUMINUM-LITHIUM-SILICON CARBIDE P/M COMPOSITES - A REVIEW.** In the present study, various investigations of the aluminum-based P/M composites containing silicon carbide as dispersoids have been examined. Because of the decrease in density produced by lithium addition in aluminum Al-Li alloy development is receiving considerable attention as possible aerospace material. Various studies on the properties and fabrication of Al-Li alloys by P/M techniques have been reviewed. Development of P/M composites based on Al-Li alloys as matrix and SiC

as second phase particles is a promising area of research for high strength and high temperature applications. In the future, these composites may replace some of the superalloys in less demanding applications. The development of Al-Li-SiC composites may lead to the consideration of other dispersoids and P/M fabrication procedures like resistance sintering. (Author abstract) 42 refs

**084276 OSPREY BREAKS NEW GROUND IN SPRAY DEPOSITION TECHNOLOGY.** The spray deposition process developed by Osprey Metals Ltd involves depositing gas atomized hot metal droplets onto a collector or mandrel where the droplets coalesce to form highly dense preforms having extremely uniform, fine grain size microstructure, which are macrosegregation free and very low in oxygen content. This gives the as-deposited preforms mechanical properties which are normally similar to those of wrought materials of similar compositions. However, because of the fine microstructure and the absence of macrosegregation, the preforms can be hot worked more easily than many conventional wrought materials, and properties of hot worked preforms are generally superior to those of conventional wrought alloys.

Williams, Bernard. *Met Powder Rep* v 42 n 10 Oct 1987 p 712, 714-716.

**084277 ADVANCED P/M ALUMINIUM ALLOY: RAPIDLY QUENCHED STRUCTURE AND DECOMPOSITION BEHAVIOUR DURING ANNEALING.** An Al-Fe-Cr-Zr alloy is currently being developed for elevated temperature service utilizing rapid solidification technology. The inert gas atomized powder has been assessed microstructurally and the solidification behavior interpreted as a function of particle size. It was significant that both fine and coarse powders exhibited structures created by solute trapping during the initial stages of solidification. An unidentified phase (or possibly phases) was detected by X-ray and electron diffraction and shown to form at cell boundaries. Zirconium was retained in solid solution during solidification of all powder structures and subsequently precipitated as fine particles of the metastable  $Al_3Zr$  phase during heat treatment. This precipitation was extremely fine and deemed suitable for elevated temperature strengthening. (Edited author abstract) 14 refs.

**084278 PRODUCTION OF FINE ALUMINIUM POWDERS BY GAS BUBBLING ATOMIZATION PROCESS.** In this process, the bubbles produced by the ejection of Ar gas into molten metal atomize it to fine liquid particles which reach an upper rotating disk cooled with liquid  $N_2$  and are crushed into finer solid particles. The obtained powders were polycrystalline and their shapes were irregular. The size of particles was distributed at values between 0.5 and 10  $\mu m$ . Mean particle size decreased with lower atomization temperature and increasing discharge of Ar gas and rotational speed. (Edited author abstract) In Japanese. 4 refs.

**084279 PILOT PRODUCTION OF RAPIDLY SOLIDIFIED ALUMINIUM ALLOY POWDERS BY GAS ATOMIZATION.** The development of the pilot plant at Eckart-Werke was sponsored by the German Federal Department of Research and Technology for the production of AlCuMg, AlZnMgCu, AlFe(Ce,Y), Al-FeNi (Mg,Zr,Ti,Mo,Cr, Cu), AlSi(Fe,Ni,Mn,Ti) by gas atomization. The maximum melt size of the plant is 60 kg. Different spray jets and several kinds of gas (argon, nitrogen, helium, gas-mixtures and air) can be used to vary the produced powder. The cooling rate of an Al 2024 was estimated for particles of different sizes and particles

atomized with different kinds of gas. For this estimation the secondary dendrite arm spacing was measured and compared with a calibration line of secondary dendrite arm spacings obtained by known cooling rates. 3 refs.

**084280 THERMAL CONSIDERATIONS ON THE RECALESCENCE OF ALLOY POWDERS.** The principles involved in the solidification of supercooled binary alloy droplets are discussed with particular emphasis on solute redistribution. The effects of alloying elements on the parameters of the thermal history of recalescing aluminum droplets are studied with the aid of enthalpy-temperature relationships. Thermal considerations indicate that the critical supercoolings to achieve partitionless solidification change modestly. The rate of calescence after nucleation is likely to be slowed down by the addition of solute. A Newtonian model for solidification of nonideal binary alloys with morphologically stable interfaces is used to study the thermal history and solute redistribution during recalescence. (Edited author abstract) 32 refs.

Levi, Carlos G. (Univ of California, Santa Barbara, CA, USA). *Metall Trans A* v 19A n 3 Mar 1988 p 687-697.

**084281 EVOLUTION OF MICROCRYSTALLINE STRUCTURES IN SUPERCOOLED METAL POWDERS.** A numerical model has been developed to study the relative effects of nucleation and growth kinetics on the evolution of ultrafine grain structures observed in some supercooled metal powders. The thermal history during solidification is analyzed using a Newtonian heat transfer formulation coupled to classical models for homogeneous nucleation and continuous growth with a diffuse interface. The results indicate that decreasing particle size increases both the supercooling prior to solidification and the thermal excursion beyond the nucleation temperature. There is a range of particle size in which the achievable supercooling are high enough to produce massive nucleation before any significant growth - and the ensuing recalescence - can take place. The probability of multiple nucleation may be evaluated, from a dimensionless parameter combining the characteristic frequencies of the nucleation, growth, and heat transfer processes at the moment of nucleation. Calculations for Al and Ni model systems confirm the experimental observation that the latter has a stronger tendency to supercool and develop microcrystalline structures. (Edited author abstract) 36 refs.

**084282 RECENT R&D OF ALUMINIUM ALLOYS FOR AIRCRAFT APPLICATIONS: PART 3. POWDER METALLURGY ALLOYS.** Because rapid solidification and mechanical alloying can extensively control the microstructure of aluminium alloys, combination of one of these powder production processes and powder metallurgy (P/M) process leads to the development of unique alloy systems with high performance. High strength alloys including 7 XXX, 2 XXX and 5 XXX alloys, low density and high modulus alloys, dispersion-strengthened alloys with high strength at elevated temperature, and wear-resistant alloys are being developed. They offer great advantages over conventional ingot metallurgy alloys. Most of them have the potential to meet the demands for enhancing the properties of aluminium alloys in the field of aircraft industries. Thus, much effort is being continued in order to apply these alloys to aircraft. This paper reviews recent trends of P/M aluminium alloys with the main focus on aircraft applications. (Author abstract) In Japanese. 61 refs.

**084283 RAPID SOLIDIFICATION AND POWDER METALLURGY AT ALLIED-SIGNAL INC.** Allied-Signal's activity in rapid solidification and powder metallurgy (RS/PM) is broad based in research, develop-

ment and applications. The activities include process development, alloy development, powder production, consolidation and fabrication and evaluation of prototype parts. This profile elaborates on current RS/PM activities in aluminum and magnesium-based alloys. (Author abstract)

Das, Santosh K. (Allied-Signal Inc, Morristown, NJ, USA). *Int J Powder Metall (Princeton NJ)* v 24 n 2 Apr 1988 p 175-183.

**084284 ADVANCED ALUMINUM ALLOYS FOR HIGH TEMPERATURE STRUCTURAL APPLICATIONS.** Advanced aluminum alloys for elevated structural applications have been developed in recent years via the powder metallurgy techniques including rapid solidification (atomization and melt spinning), mechanical alloying and metal matrix compositing. The most promising of all appear at present to be rapidly solidified Al-Fe base powder alloys. Studies conducted several years ago for a variety of potential aircraft applications have identified that substantial weight and cost savings would be obtained if these alloys were used successfully at service temperatures between 120°C and 350°C (248°F and 662°F). When compared with competitive high strength materials such as steel and titanium alloys for elevated temperature (120-350°C) applications, the relatively low machining costs and density of these aluminum alloys are very attractive. The prospect of achieving the same strength/density properties as Ti-6Al-4V at temperatures in excess of 300°C (572°F) is good. 5 refs.

**084285 DEPENDENCE OF ROLLING RESISTANCE ON STRAIN IN COMPACTING ALUMINIUM POWDER MATERIALS.** The authors examined the variation of the properties of porous sheet blanks and force characteristics of the deformation process in compacting by rolling. It is shown that a large reduction of the pressure in rolling the rapidly solidified powder materials can be utilized in selecting the technological regimes of producing sheets of composite materials with limited force characteristics of deformation, and also of components from such materials, by this type. 8 refs.

**084286 POWDER METALLURGY. A WAY FOR IMPROVING THE PERFORMANCES OF ALUMINIUM ALLOYS.** P/M of Al alloys appears thus as a very effective way for improving many engineering properties of Al alloys and is a chance for this still young metal to find applications in new areas and markets. Of particular importance are the improvements possible in terms of surface properties, temperature stability, specific strength and stiffness of Al alloys. The main challenge now is to upscale the process and bring it at an industrial scale; at this point, both technical and economical parameters are of paramount importance and emerging routes like the Spray Deposition Approach may be of interest. 7 refs.

**084287 EFFECT OF PROCESSING VARIABLES ON PARTICLE SIZE IN GAS ATOMIZATION OF RAPIDLY SOLIDIFIED ALUMINIUM POWDERS.** The performance of a 'confined' type atomizing nozzle was investigated using nitrogen, argon, and helium gases at different pressures and AA 2014 metal at varying superheats and flow rates. Helium produced the finest powders with median diameters between 14.6 and 18.5  $\mu m$ . Nitrogen powders showed an intermediate size while those made in argon were the coarsest (21-37  $\mu m$ ). Metal temperatures above 825°C led to only a small decrease in particle size which could be explained on the basis of lowered surface tension and viscosity of the melt. At lower

temperatures (775°C), possible interference from pre-mature solidification was noted. Operation at 1.56 MPa pressure offered the optimum conditions (nitrogen). There was a wastage of gas at higher pressures (2.12 MPa) and flake formation interfered at lower pressures (1.05 MPa). Powder median diameter increased in proportion to the square root of the metal flow rate and in all cases the size distribution could be satisfactorily represented by the log-normal law. The spread of the sizes, as measured by geometric standard deviation, increased at high metal flows indicating that relatively higher proportions of large particles were present in such powders. (Author abstract) 30 refs.

## Aluminum Chromium

**084288 PREPARATION OF SOME ALUMINUM ALLOYS BY MECHANICAL ALLOYING AND THEIR MECHANICAL PROPERTIES.** The mechanical alloying process is a method for producing alloys with controlled structure. Al-Cr and Al-Cr-C alloys were prepared by mechanical alloying and powder hot extrusion. Tensile strength, hardness and microstructure were investigated. The fine particles of oxides and carbides gave a high hardness and tensile strength. The alloys kept their high hardness after heating about 400°C. Tensile strength at high temperature decreased linearly up to 400°C. (Edited author abstract) In Japanese. 16 refs.

Morooka, Toshimasa (Musashi Inst of Technology, Tokyo, Jpn); Yuasa, Eiji. *Keikinzoku* v 37 n 10 Oct 1987 p 683-689.

## Aluminum Copper

**084289 EFFECT OF POROSITY ON THE VOLUME CHANGES EXPERIENCED BY Al-Cu COMPOUNDS DURING LIQUID-PHASE SINTERING.** In the Al-Cu system a linear relationship between the end and starting porosities exists only at porosities exceeding 20%. At a smaller pore content the linearity is disturbed by the presence of an irreducible oxide phase on the aluminum particles. Decreasing the starting compact porosity results in greater growth in the first stage of sintering and smaller shrinkage in the second. The extent of the compact growth preceding the shrinkage may exceed that due to atom diffusion under conditions of uniform reaction of the liquid phase on surfaces of the particles. The anomalously large compact growth in the first stage is due to a negative regrouping of particles resulting from uneven Kirkendall flow of material inside the particles. 17 refs.

**084290 P/M MATERIALS FROM SPLAT QUENCHED FLAKES OF 2024 ALUMINUM ALLOY CONTAINING TRANSITION METALS.** Improvement of conventional 2024 aluminum alloy was experimentally studied by the addition of transition metals and rapid solidification. Alloying additions were 1 to 4 wt% Fe, 2 to 6 wt%Mn and 2 to 6 wt%Ni. Rapidly solidified flakes were produced by atomizing the melt and subsequent splat quenching onto a water cooled copper roll. Consolidation was done by cold pressing, degassing and hot extrusion. Microhardness increased with the addition of transition metals due to fine particles of their eutectic compounds. P/M materials from these flakes also contained fine dispersions of eutectic compounds and showed higher hardness after annealing at high temperatures. Mn bearing material showed the highest strength and Ni bearing the lowest. However, addition of these elements reduced the age hardening of 2024 alloy. The alloys with large addition of transition metals showed higher fatigue strength than conventional 2024 alloy in high cycle fatigue. (Edited author abstract) In Japanese. 6 refs.

Makoto; Kaneko, Junichi. *Keikinzoku* v 37 n 10 Oct 1987 p 690-697.

**084291 DEVELOPMENT AND EVALUATION OF BEARING CHARACTERISTICS OF MECHANICALLY ALLOYED Al-4.5% Cu-GRAPHITE COMPOSITES.** Dispersion of graphite by MA in Al-4.5% Cu improves its bearing performance and wear resistance without any decrease in its K-factor value. For the same level of improvement in the bearing performance of Al-4.5% Cu, the amount of graphite addition decreases if it is added by MA. About 3 wt.% of graphite addition to the Al-4.5% Cu by MA is sufficient to improve its performance. 18 refs.

Sharma, A. (Malaviya Regional Engineering Coll, Jaipur, India); Soni, P.R.; Rajan, T.V. *Met Powder Rep* v 43 n 1 Jan 1988 p 37-38.

**084292 EFFECT OF SINTERING CONDITIONS ON THE STRUCTURE AND MECHANICAL PROPERTIES OF P/M ALUMINUM BASE ALLOYS.** Specimens of Al-4.4% Cu and Al-4.4% Cu-0.5% Mg were studied. A magnesium addition promotes densification of Al-Cu specimens sintered for short periods of time in the range 595-635°C. Longer sintering at 615 and 635°C results in porosity. At a temperature above 595°C Al-Cu alloys experience coarsening. Alloying with magnesium does not significantly affect the structure. A magnesium addition improves the mechanical properties of Al-Cu alloy. The extent to which magnesium alters the mechanical characteristics of heat treated Al-Cu alloys depends on sintering conditions. The highest strength - 340 MPa and  $\delta = 6\%$  - is exhibited by specimens sintered for 45 min at 595°C. 21 refs.

## Aluminum Iron

**084293 RELATIONSHIP BETWEEN STRUCTURE AND MECHANICAL PROPERTIES OF Al-Fe POWDER METALLURGY ALLOYS.** The relationship between structure and mechanical properties of extruded Al-2-10%Fe powder metallurgy alloys was investigated. The yield strength is related to the volume fraction of dispersoids ( $V_p$ ) and the average dispersoid radius ( $r$ ). This relationship suggests that higher  $V_p$  and smaller  $r$  result in higher strength. Increase of Fe content raises the strength because of the increase of volume fraction of dispersoids. Annealing above 400°C lowers the strength of Al-8%Fe alloy because of coarsening of dispersoids. (Edited author abstract) In Japanese. 11 refs.

Shibue, Kazuhisa (Sumitomo Light Metal Industries Ltd, Nagoya, Jpn); Sano, Hideo; Yamauchi, Shigenori. *Keikinzoku* v 37 n 10 Oct 1987 p 698-703.

**084294 DEVELOPMENT OF ELEVATED TEMPERATURE P/M ALUMINUM ALLOY BY RAPID SOLIDIFICATION PROCESSING.** Al-Fe system alloys were investigated from the viewpoints of solid solubility, diffusion coefficient, temperature of liquidus and material cost. The mechanical properties at room and elevated temperature were evaluated in various Al-Fe system alloys. Al-8%Fe-2%V-2%Mo-1%Zr alloy was superior to the conventional 2618 alloy in room and elevated temperature tensile strength, thermal stability of hardness, and fatigue and creep properties. The properties were due to Al-Fe-V-Mo, Al-Fe and Al-Zr system dispersoids. (Edited author abstract) In Japanese. 20 refs.

Yamauchi, Shigenori (Sumitomo Light Metal Industries Ltd, Nagoya, Jpn); Shibue, Kazuhisa; Sano, Hideo; Ito, Kiyofumi; Inumaru, Susumu. *Keikinzoku* v 37 n 10 Oct 1987 p 704-709.

**084295 RAPIDLY SOLIDIFIED Al-Fe ALLOY FLAKES BY ATOMIZATION-ROLLING PROCESS.** Al-2,4,6,8 and 10%Fe alloys were rapidly solidified by means of atomization-rolling which is a combined process

of gas atomization using a single roller. Microstructure of the flake was finer than that of atomized powder. From the cell spacing of the flake, the cooling rate is estimated at  $10^5$ - $10^7$ °C/sec. The lattice constant decreased with Fe content and reached a constant value beyond 4% Fe content. The solubility of Fe was estimated at 1.4% in the flake containing more than 4%. Hardness increased with Fe content. It was higher than that of gas atomized powder. In Japanese. 14 refs.

Shibue, Kazuhisa (Sumitomo Light Metal Industries Ltd, Jpn); Sano, Hideo; Yamauchi, Shigenori; Inumaru, Susumu. *Sumitomo Keikinzoku Gihō* v 28 n 4 Oct 1987 p 181-186.

**084296 MECHANICAL PROPERTIES OF THE RAPIDLY SOLIDIFIED Al-Fe BINARY ALLOYS BY ATOMIZATION-ROLLING PROCESS.** In this work, Al-Fe alloy flakes solidified at a cooling rate of  $10^5$ - $10^7$ °C/sec were consolidated and the mechanical properties and microstructures were evaluated in comparison with alloys made by gas atomization. Al-2-10wt%Fe alloys had higher strength at room temperature. Al-8wt%Fe had higher elevated temperature strength up to 350°C. Al-8wt%Fe had finer dispersoids of  $Al_3Fe$  or  $Al_6Fe$ . Higher strength is attributed to the fine dispersion of Al-Fe intermetallic compounds due to a higher cooling rate. (Edited author abstract) In Japanese. 5 refs.

Sano, Hideo (Sumitomo Light Metal Industries Ltd, Jpn); Shibue, Kazuhisa; Yamauchi, Shigenori; Inumaru, Susumu. *Sumitomo Keikinzoku Gihō* v 28 n 4 Oct 1987 p 187-192.

**084297 ELEVATED-TEMPERATURE Al ALLOYS FOR AIRCRAFT STRUCTURE.** To improve the performance characteristics of advanced aerospace vehicles, lower-density, stronger, stiffer and higher-temperature materials are being studied. Elevated-temperature powder metallurgy (P/M) aluminum alloys are being developed to replace titanium aircraft structure materials for operation in the 300-600°F temperature range. Typical mechanical properties of P/M Al-Fe-Ce and Al-Fe-V-Si alloys are superior to those of conventional materials. Cost savings of fifty to seventy percent have been projected for these alloys which can be fabricated and processed using methods similar to those used in the production of conventional aluminum. (Edited author abstract) 5 refs.

## Aluminum Iron Alloys

**084298 CHARACTERISTICS OF RAPIDLY SOLIDIFIED Al-8wt%Fe POWDERS PRODUCTION BY FLAME SPRAYING METHOD.** Al powders containing 8wt%Fe were solidified rapidly by collision onto a stainless steel vessel cooled by ice water. Characterizations of these powders were carried out by X-ray diffraction analysis, electron microscopic observations and electron probe X-ray microanalysis. The main phases formed by flame spraying were composed of  $\alpha$ -Al, stable  $Al_3Fe$  and metastable  $Al_mFe$  phases. A metastable  $Al_6Fe$  phase was observed to form at relatively low cooling rates. (Edited author abstract) In Japanese. 36 refs.

Yokota, Masaru; Ueda, Taiji; Asakura, Tadashi; Shoji, Keichiro. *J Jpn Soc Powder Powder Metall* v 34 n 6 Aug 1987 p 248-253.

**084299 INFLUENCE OF ANNEALING ON MECHANICAL PROPERTIES OF FLAME SPRAYED AND RAPIDLY SOLIDIFIED Al-8wt%Fe ALLOY POWDER EXTRUDED MATERIALS.** Mechanical properties of as-extruded materials were tensile strength 37 kgf/mm<sup>2</sup>, elongation 9.5%, proof strength (0.2%) 27 kgf/mm<sup>2</sup> and hardness 100 kgf/mm<sup>2</sup>. These properties at room temperature were maintained up to 773 K of annealing for 1 hour. Beyond that, except for elongation, the other mechanical properties decreased with annealing temperature. At 773 K, hardness decreased with anneal-

ing time. The same tendency against annealing time was observed in the X-ray diffraction experiment. The mechanism of strengthening is thought to be dispersion hardening. (Edited author abstract) In Japanese. 25 refs.

Yokota, Masaru; Ueda, Taiji; Kuroda, Hayao; Shoji, Keiichiro. *J Jpn Soc Powder Metall* v 34 n 6 Aug 1987 p 254-258.

**084300 MECHANICAL ALLOYING AND CONSOLIDATION OF ALUMINUM-IRON SYSTEM.** Pure aluminum and iron powders were processed by mechanical alloying and consolidated by strained powder rolling (SPR). Iron particles are dispersed finely in the aluminum powders after long mechanical alloying time. Their number increases with increasing iron content. The composite powders processed less than 172 ks are well consolidated by the SPR method. In the case of specimens powder processed for 130 ks and consolidated at 673 K by the SPR method, tensile strength increases almost linearly but elongation decreases little with iron content up to 8%. The tensile strength is about 550 MPa and elongation is about 1.6%. (Edited author abstract) 13 refs.

Bin, Huang (Kyoto Univ, Kyoto, Jpn); Kobayashi, Kojiro F.; Shingu, Hideo P. *Keikinzoku* v 38 n 3 Mar 1988 p 165-171.

**084301 DEVELOPMENT OF Al-Re P/M ALLOY BY ATOMIZATION-ROLLING PROCESS.** Ultra-rapid solidification is required instead of gas atomization in order to modify the properties of P/M alloys, especially dispersion-strengthened Al-Fe alloys. In the present work, various Al-Fe alloys were rapidly solidified by means of atomization-rolling and consolidated by hot extrusion. Microstructure and tensile properties were evaluated in comparison with gas atomization. The cooling rate of atomization-rolling was  $10^5$ - $10^7$ °C/sec which was higher than gas atomization. Extruded alloys had higher strength at room and elevated temperature due to finer dispersion of intermetallic compounds. Al-8 percent Fe-2 percent V-2 percent Mo-1 percent Zr alloy had high strength at elevated temperature. (Edited author abstract). 7 Refs. In Japanese.

Yamauchi, Shigenori; Shibue, Kazuhisa; Sano, Hideo; Ohkubo, Yoshimasa. *J Jpn Soc Powder Metall* v 35 n 3 Apr 1988 p 87-90.

**084302 RELATIONSHIP BETWEEN MICROSTRUCTURE AND MECHANICAL PROPERTIES OF Al-Fe POWDER METALLURGY ALLOYS.** The relationship between microstructure and mechanical properties of extruded Al-2-10%Fe P/M alloys was investigated. The results obtained were as follows: Yield strength ( $\sigma_{0.2}$ ) is related to volume fraction of dispersoids ( $V_d$ ) and average dispersoid radius ( $r$ ):  $\sigma_{0.2} \propto V_d^{1/2} \cdot r^{-1}$ . This relationship suggests that higher  $V_d$  or smaller  $r$  results in higher strength. Increase of Fe content raises the strength of Al-Fe alloy because of the increase of volume fraction of dispersoids. Annealing at the temperature above 400°C lowers the strength of Al-8%Fe alloy according to coarsening of dispersoids. (Author abstract). 12 Refs. In Japanese.

Shibue, Kazuhisa; Sano, Hideo; Yamauchi, Shigenori. *Sumitomo Keikinzoku Gihō* v 29 n 2 Apr 1988 p 14-21.

**084303 PROPERTIES OF GAS ATOMIZED Al-Fe POWDERS AND ITS VARIATION BY ANNEALING.** Properties of Ar gas atomized powders of Al-8 mass percent Fe alloy and its variation by annealing have been examined by means of scanning electron microscopy, transmission electron microscopy and hardness measurement. A cell structure having metastable phase  $Al_3Fe$  at its boundaries forms in particles in the size smaller than 105  $\mu m$ , besides a primary crystallized intermetallic compound  $Al_3Fe$  predominantly exists in the particles larger than 105  $\mu m$ . The hardness of powders increases with decreasing particle diameter due to the refinement of cell structure. The annealing at temperature above 400°C accelerates the decomposition of cell structure and the formation of granular intermetallic compound, both of which result in the notable softening in the small size

particles.  $Al_3Fe$  which has been at cell boundaries transforms to  $Al_3Fe$  by the annealing above 450°C. Even after high temperature annealing, large particles show only a slight decrease in hardness keeping low values due to small change in the coarse structure. (Author abstract). 16 Refs. In Japanese.

#### Aluminum Iron Nickel Alloys

**084304 PROPERTIES OF CONTINUOUSLY EXTRUDED Al-Fe-Ni-Cu-Mg ALLOY POWDERS.** Alloys of Al-2.2 percent Cu-1.5 percent Mg with equal amounts of Fe and Ni addition up to 7 percent each were argon gas-atomized to fine powders, and continuously extruded by a Conform machine. The extrudates showed superior strength, heat resistance and high modulus of elasticity and also exhibited low thermal expansion coefficients and good wear resistance. The extrudates from rapidly solidified alloy powders were dispersion hardened by fine dispersoids of  $Al_3FeNi$  and age hardened by Al-Cu-Mg precipitates. High volume fraction of  $Al_3FeNi$  phase also caused high modulus, low thermal expansion and good wear resistance. (Author abstract). 5 Refs. In Japanese.

Kobayashi, Yasuo (Mitsubishi Aluminum Co, Susono, Jpn); Yoda, Michioh; Suzuki, Yoshiya. *Keikinzoku* v 38 n 6 Jun 1988 p 338-344.

#### Aluminum Lithium

**084305 ALUMINUM-LITHIUM POWDER METALLURGY ALLOYS WITH IMPROVED TOUGHNESS.** A technique has been developed for increasing the toughness of Al-Li products made by powder metallurgy. The technique which involved forming a duplex structure by the addition of unalloyed aluminum powder to Al-Li powder before compaction was evaluated with Al-Li-Cu-Mg-Zr alloys (A18090). The strength, ductility, toughness, and short transverse stress corrosion resistance were determined. The addition of 15 pct aluminum to A18090 aged at 422 K for 40 hours produced an increase in impact toughness of 215 pct at the expense of a drop in yield strength of 11 pct. The alloys with a duplex structure had superior longitudinal strength-toughness combinations to ingot materials of similar composition processed identically. (Edited author abstract) 22 refs.

**084306 EFFECT OF SILICON, MAGNESIUM, COBALT AND IRON ADDITIONS ON THE MICROSTRUCTURE OF Al-Li CENTRIFUGALLY ATOMIZED POWDERS.** The effect of the addition of silicon (up to 4 wt%), magnesium (up to 7.25 wt%), cobalt (up to 0.8 wt%) and iron (up to 1.5 wt%) on the microstructure of as-solidified Al-3 wt% Li powders produced by centrifugal atomization in a helium atmosphere has been studied by optical, scanning electron and transmission electron microscopy. The microstructure changes from dendritic in the case of Al-Li and Al-Li-Mg alloys to a eutectic (Al + AlLiSi) mixture in the Al-Li-Si alloy to a cellular structure for the Al-Li-Co alloy and results in the direct nucleation of coarse intermetallic  $Al_6Fe$  from the melt followed by subsequent growth in the case of Al-Li-Fe alloy. (Author abstract) 7 refs.

**084307 INCO UNVEILS NEW PRODUCTION FACILITY FOR MECHANICALLY ALLOYED ALU-**

**MINIUM PRODUCTS.** IncoMAP, a division of Inco Alloys International, has started production of mechanically alloyed aluminum at a new plant in Pittsboro, North Carolina. The article describes the manufacturing facilities used at Pittsboro and the properties of the mechanically alloyed aluminum which are either in commercial production or still undergoing development and testing. The alloys described are AL-905 XL, AL-9052 and composites based on the latter.

Schelleng, D. *Met Powder Rep* v 43 n 4 Apr 1988 p 239-241.

#### Aluminum Magnesium Iron Alloys

**084308 STRUCTURAL INHOMOGENEITY DURING PRODUCTION AND PROCESSING OF RAPIDLY SOLIDIFIED Al-6Mg-5Fe ALLOY.** Considerable microstructural differences have been noted from among different powder particles and from within the same particles. Three typical microstructures were observed; small particles exhibited a microcellular structure, medium-sized particles a dual morphology of microcellular and cellular structure, whilst in the large particles coarse intermetallics were formed, acting as nucleation sites for a cellular structure. Apart from Al3other phases were detected  $Fe_4Al_{13}$ , (Fe, Mn) $Al_6$  and an unidentified phase termed 'F'. The formation of both spheres and needle particles was promoted at high temperatures irrespective of the type of phase ( $Fe_4Al_{13}$  or (Fe, Mn) $Al_6$ ). The heterogeneity of the microstructural features was maintained during subsequent consolidation via extrusion. The influence of heating and deformation modifies the microstructures but was insufficient to produce a uniform microstructure. The decomposition behavior has been examined. The heterogeneities in the extrudate could be related to the microstructure and solidification behavior during atomization. (Edited author abstract) 18 refs.

#### Aluminum Manganese Chromium Alloys

**084309 MASS AND HEAT TRANSFER DURING ULTRASONIC GAS ATOMIZATION.** Fluid flow behavior during ultrasonic gas atomization was studied. Gas velocity was measured by pilot tube experiments and Schlieren photography. Powder particle velocities were calculated. The gas velocity reaches 1700 m/s (Mach 1.7) in the supersonic flow region for helium gas at a backing pressure of 6.9 MPa. A 15  $\mu m$  diameter Al-5mass% Mn-2.5mass% Cr powder particle is accelerated to a maximum velocity of 1200 m/s while for a 150  $\mu m$  diameter particle, the maximum particle velocity is about 400 m/s. Solidification studies were carried out by collecting powder particles at different flight distances from the atomization nozzle. A comparison between a theoretical solidification model and the experimental result shows good agreement. (Author abstract) 22 refs.

#### Aluminum Silicon

**084310 PROPERTIES OF Al-Si-X P/M ALLOYS USING RAPIDLY SOLIDIFIED POWDERS.** The P/M alloys were based on a hypereutectic Al-Si system to which transition elements (Fe, Ni, Mn) were added up to 10 wt.% as well as 3 wt.%Cu and 1 wt.%Mg in order to improve the strength at elevated and room temperature, respectively. Addition of a transition element caused an intermetallic compound to be formed. Extruded P/M alloys had fine and homogeneous structures which are not obtainable from ingot metallurgy alloys. The Al-Si P/M alloys were higher in tensile I/M alloys of the same composition. An addition of transition element improved strength and thermal stability at elevated temperature. Addition of Si and SiC particles improved seizure and wear properties. The alloys containing more than 20

wt% Si and a transition element had a low thermal expansion coefficient. (Edited author abstract) In Japanese. 8 refs.

**084311 PRODUCTION AND WEAR CHARACTERISTICS OF SI-DISPERSED ALUMINUM COMPOSITE PREPARED BY POWDER EXTRUSION.** Al-Si-X composites containing dispersed Si particles were prepared by powder extrusion. Wear characteristics were investigated by a pin-drum type wear testing machine under lubrication of compressor oil. The wear resistance of the composites is higher than that of the base material because of its large Si particles. In the case of Si-dispersed composites, wear resistance increases with increasing hardness of the composites. (Edited author abstract) In Japanese. 7 refs.

Fujita, Tatsuo (Riken Corp, Kashiwazaki, Jpn); Kiyota, Fumio; Hirano, Tadao; Kojima, Yo. *Keikinzoku* v 37 n 10 Oct 1987 p 677-682.

**084312 EFFECTS OF TEMPERATURE AND STRAIN RATE ON DUCTILITY AND FLOW STRESS OF A RAPIDLY SOLIDIFIED HYPEREUTECTIC AL-SI P/M ALLOY.** A hypereutectic Al-Si P/M alloy can be produced in which fine silicon particles with a size on the order of a few micrometres are uniformly dispersed. Hot forging in the temperature range 400-500°C is recommended for plastic working because the improvement in ductility and the decrease in flow stress are accelerated with the increase in temperature. The required working pressure can be determined from a nomogram. 5 refs.

Hirai, Yukio (Government Industrial Research Inst, Nagoya, Jpn); Kanayama, Kouzou; Nakamura, Mamoru; Sano, Hideo; Kubo, Katsushi. *J Mater Sci Lett* v 7 n 5 May 1988 p 517-519.

## Aluminum Silicon Alloys

**084313 EFFECTS OF DEFORMATION TEMPERATURE AND STRAIN-RATE ON WORKABILITY OF A RAPIDLY SOLIDIFIED HYPEREUTECTIC AL-SI/P/M ALLOYS.** The flow stress and ductility of an aluminum P/M alloy prepared by hot extrusion from rapidly solidified powders of an Al-20Si-5Fe-2Cu-1Mg-1Mn alloy were investigated by compression and tensile tests to clarify its workability. Flow stress decreases and critical amount of strain for deformation without cracking increases with deformation temperature. The increase in strain rates increases flow stress at a higher temperature than 180°C.  $\sigma$  and strain rate  $\epsilon$  is described as  $\sigma = K\epsilon^m$ . The strain sensitivity exponent increases with deformation temperature and becomes about 0.3 at 480°C. A nomogram to predict the flow stress at a certain ram speed and temperature has been drawn. (Author abstract) 7 refs.

**084314 CONSOLIDATION OF RAPIDLY SOLIDIFIED AL-SI POWDERS BY THE STRAINED POWDER ROLLING METHOD.** Rapidly solidified Al-Si ribbons prepared by the single roller method were pulverized by a vibration mill. The milled powders were consolidated at different temperatures by the strained powder rolling method. P/M alloys have a density more than 95% of that of metal mold cast alloys. Hypereutectic P/M alloys have a uniform distribution of fine Si particles in the structure. P/M alloys harden with increasing Si content and soften at higher rolling temperatures. Tensile strength and elongation are higher than those of cast alloys containing Si 20 at% or more. A 30 at% Si P/M alloy has a tensile strength of about 33 kg/mm<sup>2</sup> and elongation of about 5%. (Edited author abstract) 15 refs. In Japanese.

## Aluminum Zinc Nickel Zirconium Alloys

**084318 DEFORMATION AND MECHANICAL PROPERTIES OF A RAPIDLY SOLIDIFIED 7075-TYPE ALLOY.** An experimental modified 7075-type aluminum alloy containing 1% Ni plus 0.8% Zr was prepared using inert gas atomization. The alloy was hot consolidated by a blank (1:1) upset. The upset material was then extruded at an area reduction ratio of 13:1. A re-extrusion of the material at 16:1 was performed to yield a net reduction of 200:1. The alloy showed a fine microstructure with a grain size of approximately 2  $\mu$ m. Very high strength and improved fatigue performance were achieved when compared with the ingot metallurgy 7075 alloy. Further working by extrusion or hot forging redistributed deleterious oxide stringers but did not significantly change mechanical properties. The deformation-mechanical property relationship is discussed. (Author abstract). 10 Refs.

## Amorphous

**084319 GLASS FORMATION IN MECHANICALLY ALLOYED TRANSITION METAL-TITANIUM ALLOYS.** The formation of amorphous powders by mechanical alloying of crystalline elemental powders is

investigated for a series of transition metal-titanium alloys. Completely amorphous powders are received in the Ni-Ti, Co-Ti and Cu-Ti systems. Partial amorphization is possible in the Fe-Ti, Mn-Ti and Cr-Ti systems whereas, for V-Ti, mechanical alloying results in a crystalline solid solution. The alloying and amorphization process is monitored by X-ray diffraction, magnetization measurements and thermal analysis. The experimental results are compared with calculated free enthalpy diagrams. It is shown that the amorphization depends strongly on a large negative heat of mixing. (Author abstract) 14 refs.

**Applications** See Also POLYIMIDES—Physical Properties.

**084320 NEAR NET SHAPE FORMS SAVINGS.** This paper discusses the near net shape processes of cold forming and powder metallurgy which offer the ability to reduce cost and assembly time by combining the functions of what otherwise would be two or more parts into one, and at the same time greatly reduce material waste as compared to machined or stamped parts. Cold forming is a forging process using a die or a succession of dies, to displace the metal in a length of rod or wire, to form a diameter or shape different from the original. The metal is forced to flow around and into shape-forming dies. The powder metal process also uses dies, but the material is very fine particles (2 to 8 mils diameter) of metal. These particles are blended to form the desired alloy and mixed with a lubricant.

Schwartz, Walter H. (Assembly Engineering, Wheaton, IL, USA). *Assem Eng* v 31 n 7 Jul 1988 p 34-35.

## Beryllium

**084321 HIP BERYLLIUM ACHIEVES FULL COMMERCIAL STATUS.** This paper describes the experience in producing beryllium components by two basic processes. The first of these is direct HIPing of powder in a container. The alternate approach is containerless HIPing, where the parts are cold pressed (die or isopressed), vacuum sintered, and then HIPed. The relative economics of conventional versus HIP processing of several production parts is compared. (Edited author abstract) 5 refs.

## Boron Compounds

**084322 AMBIENT PRETREATMENT EFFECT ON HIGH PRESSURE SINTERING OF c-BN USING h-BN AS A STARTING POWDER.** Single phase sintered compact of c-BN was prepared by high pressure and temperature treatment (7 GPa, 1700°C, 30 min) of h-BN powder mixed with 30 wt percent c-BN powder. An induced transformation from h-BN to c-BN was affected by ambient pretreatment in a hydrogen and nitrogen stream. The c-BN sintered compact showed an homogeneous microstructure composed of directly bonded grains of 0.5-1.0  $\mu$ m in particle size. Density and microhardness were 3.41 g/cm<sup>3</sup> and 5100 kg/mm<sup>2</sup>, respectively. The dielectric constant of the c-BN compact decreased monotonously with increase in frequency and showed a constant value of 10.0 above a frequency of 1 MHz. (Edited author abstract). 3 Refs. In Japanese.

## Bronze

**084323 INVESTIGATION ON P/M POROUS MATERIALS USED FOR FOUNDRY TOOLS AND DEVICES.** A rudimentary experiment was tried on the P/M bronze filtering components used for cold box tools by investigating the technologies of triethylamine air spray

cold boxes. It has been found that production costs can be decreased and casting qualities can be improved by using P/M bronze filtering components as venting units. This is a trial to extend the application range for these porous materials. (Author abstract) 1 ref. In Chinese.

Chang, Zhongmin. *Fenmo Yejin Jishu* v 5 n 2 May 1987 p 93-96.

**084324 INFLUENCE OF THE PARTICLE SIZE COMPOSITION OF 6-63 BRONZE POWDER BY GAS ATOMIZATION UPON APPARENT DENSITY AND COMPRESSIBILITY.** The present paper has concisely discussed the influence of particle size upon the apparent density, flow rate and compressibility of gas-atomized 6-63 bronze powder. The more fine particles ( $-320+400$  mesh size), the greater is the apparent density. The more coarse particles, the greater is the flow rate. When the composition of the fine powder is about 70%, the density of the compressed unit reaches its maximum. (Edited author abstract) In Chinese. 2 refs.

## Carbon Steel

**084325 HIGH-STRENGTH CARBON STEELS WITH HEREDITARY FINE CRYSTAL STRUCTURE. IV. SOME TRAITS OF THE STRUCTURE FORMING PROCESS IN THE HEAT TREATMENT OF POWDERED CARBON STEELS.** The present work deals with the characteristic structures of carbon steels (0.95% C), the fracture surface of specimens (fractographic investigations), and on the basis of that the authors determine the essence of the strengthening of the alloy, ways of improving further the mechanical properties and their stability. The induced structural states of the grain boundaries endow the material with greater strength than the grain boundaries. In some cases there is intergranular failure, in other cases there is brittle failure. Ductile intergranular failure is preferable because with the optimal ratio of the dimension, density of segregates, and width of the depleted zone material with high strength and fracture toughness may be obtained whereas brittle intergranular failure cannot ensure high values of these characteristics. Consequently, revealing the peculiarities of the processes of strength formation of a high-strength alloy and investigation of the fracture surfaces make it possible to shed light on the essence of the strengthening of a material, and also to determine ways of further increasing the load bearing capacity of the steel. 4 refs.

**Chromium** See Also CHROMIUM COMPOUNDS—Heat Treatment.

**084326 TENSILE DEFORMATION BEHAVIOR OF SINTERED CHROMIUM.** Tensile properties of sintered powder chromium produced by a cold isostatic press (CIP) and a hot isostatic press (HIP) were examined to find conditions favorable to plastic working of the sintered chromium. Specimens A and B<sub>1</sub> taken from a sintered ingot A and half of an ingot B were annealed at 1823 K, higher than the 1473 K encountered in the HIP. Specimen B<sub>2</sub> from the remainder of ingot B was not heat treated. Transition from ductile to brittle fracture occurred in a small range of temperature and at the higher temperature in testing at the higher speed of deformation. Ductile-to-brittle transition temperature of specimen B<sub>1</sub> was lower than that of specimen B<sub>2</sub> suggesting that the annealing at 1823 K is effective in lowering the transition temperature. A small plastic tensile prestrain given to a specimen at a temperature slightly beyond its transition temperature reduced brittleness. This prestraining effect comes from free dislocations generated in the prestrained specimen. At temperatures between 700 K to 1023 K, flow stress never changed even when the strain rate was increased from  $1.7 \times 10^{-4} \text{ s}^{-1}$  to  $1.7 \times 10^{-1} \text{ s}^{-1}$ . The

decrease in stress with increasing temperature was small. (Edited author abstract) 28 refs. In Japanese.

## Chromium Compounds

**084327 SINTERING OF CHROMIUM BORIDE BASE MATERIALS.** A study was made of conditions of production of chromium boride base materials with iron and nickel base binders. Sintering was performed for 0.5-2.0 h in the temperature range 1000-1700°C. The chromium boride-iron-nickel alloys had a multiphase structure consisting of grains of the chromium boride CrB, the iron boride FeB with a microhardness of about 11,000 MPa, and the binary boride  $(\text{Cr}_2\text{Ni})_x\text{B}_y$  with a microhardness of 18,500 MPa. The chromium boride base material with the nickel-chromium alloy binder as had a multiphase structure consisting of grains of the chromium boride CrB with a microhardness of 11,000-12,900 MPa and the binary boride  $(\text{Cr}_2\text{Ni})_x\text{B}_y$  with a microhardness of 19,000 MPa. 5 refs.

## Cobalt

**084328 ON THE SINTERING PROCESS OF COBALT AND DIAMOND MIXED POWDER COMPOUNDS.** The sintering process of Co and diamond mixed powder compacts in normal sintering and hot pressing was investigated by dilatometric and microscopic examinations. In the case of normal sintering, the shrinkage of Co powder compact started at 500°C and finished at about 1200°C. The shrinkage behavior of Co and diamond mixed powder compact was similar to that of the Co powder compact. In the case of hot pressing, shrinkage started at about 200°C and finished at 900°C. The Co and diamond mixed powder compact was denser than normally sintered compacts. (Edited author abstract). 5 Refs. In Japanese.

**Compacting** See Also METAL FORMING—Pressing; NICKEL TITANIUM ALLOYS—Phase Transitions; POWDER METAL PRODUCTS—Amorphous; POWDERS—Compaction; POWDERS—Magnetic Field Effects.

**084330 POWDER METALLURGY: A TECHNOLOGY FOR ALL INDUSTRIES.** In the future the specialist materials such as the carbide producers will meet increasing competition from alternatives. The technology which will dictate the development of this position is undoubtedly that of surface coating. Once the final performance is determined to a larger extent by its surface only, the use of alternative substrates becomes competitive where such alternatives may be used to reduce costs. Finally, whilst the development of magnetic materials was precluded by space from all but superficial mention, a speculation for the future may perhaps be permitted. Very rapid strides in the performance of both soft and permanent magnets have been achieved by powder methods. The pace of development continues to be very significant. There are indications that major developments are well

along the road. Imagine therefore the impact of a magnet with the best performance available currently, but only a third of present size. This development will surely be apparent within the next ten years.

Brown, Gordon T. (GKN Technology Ltd). *Steel Times* v 215 n 10 Oct 1987.

**084331 COMPARATIVE EVALUATION OF LUBRICANTS FOR FERROUS STRUCTURAL ALLOYS.** Lubricants are used in Powder metallurgy for minimizing die wear and aiding powder handling. In this study a performance evaluation was conducted using a statistical experimental design with three premixed lubricants (Acrawax C at 0.75 wt%, Glycolube PM-100 at 0.50 and 0.75 wt%, and Lubrazinc W zinc stearate at 0.75 wt%). These combinations were selected based on earlier testing involving several lubricants at concentrations ranging from 0.25 to 1.00 wt%. The lubricants were applied to a conventional ferrous alloy (FC-0208) of 2 wt% Cu and 0.8 wt% C using a water atomized iron powder. (Edited author abstract) 24 refs.

**084333 COMPACTIBILITY AND STRENGTH OF ROLLED STRIP FROM POWDERS (REVIEW).** By compactibility is meant the ability of a compact to retain its shape in a given porosity range. The compactibility of a powder depends on its porosity in the loosely poured state, physical condition, particle size distribution, particle shape and the presence of surface oxides. The review covers research published in the USSR and elsewhere. 42 refs.

Radchenko, A.K. (Acad of Sciences of the Ukrainian SSR, USSR); Katus, O.A. *Sov Powder Metall Met Ceram* v 26 n 7 Jul 1987 p 523-529.

**084334 POWDER FLOW DURING DYNAMIC AND QUASISTATIC COMPACTION.** An experimental study has been made of the flow of metal powders in an axisymmetric die incorporating a shoulder marking an abrupt reduction of diameter in the direction of compaction. A comparison has been made between powder flow in quasistatic and dynamic (shock wave) compaction when both methods produce a compact of the same average density. With the commercial grades of aluminum, iron, and copper powders studied, higher peak pressures were necessary during dynamic compaction to produce compacts with the same average density as those made quasistatically. Compacts made using dynamic compaction had a more uniform density distribution and were denser and harder near the die walls below the shoulder. With the powders that more strongly work hardened, closed shear surfaces were formed near the shoulder when compacted dynamically. (Edited author abstract) 10 refs.

Page, N.W. (Univ of Queensland, Brisbane, Aust); Killen, P.D. *Powder Metall* v 30 n 4 1987 p 233-239.

**084335 DEVELOPMENT OF NEW MODEL FOR COMPACTION OF POWDERS.** A theoretical model for compaction of powders has been proposed based on

the contribution of two different types of mechanisms. The first type is the rearrangement of powder particles which essentially acts at low compacting pressures. The second includes plastic deformation, fragmentation, or a combination of the two processes. The equations derived have been applied to the load-displacement curve obtained by pressing the powders in a die on a mechanical testing machine and recording the ram travel and the transmitted load. Tests on different kinds of materials (organic compounds, magnesium oxide, flint clays, metallic powders) showed that the proposed theoretical model gives a good description of the compaction process. The constants in the derived equations have been combined to obtain reliable parameters (maximum density attainable, compaction ratio). (Author abstract) 9 refs.

Cytermann, R. (IMI Inst for Research & Development, Haifa, Isr); Geva, R. *Powder Metall* v 30 n 4 1987 p 256-260.

**084336 INFLUENCE OF SMALL DIE WIDTH ON FILLING AND COMPACTING DENSITIES.** Experiments conducted to establish the influence of small die openings on actual filling density are reported. A special apparatus consisting of rectangular dies of various widths has been utilized with copper and mixed elemental bronze powders. The results show that filling densities decrease with decreasing die opening. The angle between sense of motion in filling and main die axis also influences the filling density through rebounds during powder fall; these rebounds play a positive role. The changing quantity of powder entering various dies can be explained by assuming that a boundary layer is present on the die surfaces. A simple theory, including a hydraulic radius of 'compacting' area, has been proposed and the corresponding formulae for different die geometries derived. The theoretical lines are in good agreement with the results of experimental tests. (Edited author abstract) 3 refs.

Bocchini, G.F. (Hoganas Italia srl, Como, Italy). *Powder Metall* v 30 n 4 1987 p 261-266.

**084337 DIE WALL LUBRICATION FOR POWDER COMPACTION: A FEASIBLE SOLUTION?** The development of an automatic die wall lubrication system for use during powder compaction of ferrous based materials is described. The technique, employing EP oil fed to the die wall interface under slight air pressure and augmented by the action of the toolset, appears to work well. Following laboratory scale development of the technique, involving lubricant selection, satisfactory works trials have been implemented. Five thousand simple preforms for subsequent powder forging and 2000 green compacts for a commercial sintered component of some geometric complexity have been produced in a modified production toolset. (Author abstract) 12 refs.

James, B.A. (GKN Technology Ltd, Wolverhampton, Engl). *Powder Metall* v 30 n 4 1987 p 273-280.

**084338 DENSITY-ENERGY RELATIONSHIPS IN EXPLOSIVE COMPACTION OF METAL POWDERS.** Powders of copper, iron, APK1 superalloy, and RSR aluminum alloy have been compacted in steel tubes of varying wall thickness using Trimonite explosive. In compaction tests, the energy required to compact the powder was determined by subtracting the tube deformation energy from the total initial kinetic energy of the tube. The results show that relationships exist between the specific kinetic energy applied to the powder and the compacted density achieved. These relationships are similar to relationships established between applied pressure and compacted density in isostatic and die compaction. (Edited author abstract) 15 refs.

**084339 HOT COMPACTION EQUATIONS FOR METAL POWDERS AND POROUS PREFORMS.** Theoretical compaction equations for preheated metal powders and porous preforms are formulated from a micromechanical (hollow sphere) model with a temperature dependent strain hardening law. These equations

provide a useful means to predict the pressure-relative density relation during hot compaction at various preheating temperatures. One of these hot compaction equations gives the pressure-relative density relation of Shapero and Kolthoff and of Konopicky. Theoretical predictions are compared with experimental data for copper and beryllia powder. (Edited author abstract) 34 refs.

**084340 OPTIMISATION OF THE COMPACTING PROCESS OF P/M PRODUCTS.** A lot of parameters have to be taken into consideration when planning the compacting device of a P/M production. This is shown in the following contribution. Economic aspects are dealt with first, followed by a detailed analysis of the shaping process with regard to the compaction processes. There, the correct quality of the powder is of great importance, which is described separately. Furthermore, the two basic types of press design - mechanically or hydraulically driven - are discussed thoroughly. Depending on the production goal, both can display certain advantages. (Author abstract)

**084341 HIGH-SPEED COMPUTER CONTROLLED ROBOTIC LOADING SYSTEM.** Robotic loading or pick and place systems have become an important part of modern automation in recent years. The high speed systems have been designed for the powder compacting industry to load parts from a press or feeding machine one at a time or a row at a time at up to 60 parts or rows of parts per minute. Speeds of up to 100 parts or rows of parts are possible for special applications. The article describes the equipment and its operation.

**084342 THEORETICAL STUDY ON THE IMPACT COMPACTION OF METAL POWDERS.** A theoretical investigation was made on the impact compaction of metal powders based on dynamics and rheology. The stress, displacement and acting time exerted on the powder by a drop hammer were measured by using dynamics electrometry controlled by a single-board microcomputer. The results obtained are as follows: a) The maximum stress produced by a dropping hammer with a certain kinetic energy and the acting time depend on the hammer weight, the filling weight of the powder in the die and the degree of deformation of the powder. The green density depends on the maximum impact stress and acting time, but it does not correspond to the impact kinetic energy. b) The relationship between stress and strain on impact compaction may be described by the nonlinear visco-elastic model derived by Professor Huang Peiyun. The rheologic parameters of Fe, Cu, Sn and Mo powders are calculated by a computer. The calculation shows that theoretical and experimental data are in satisfactory agreement. (Edited author abstract) 9 refs.

**084343 THEORETICAL STUDY ON THE COMPACTION OF METAL POWDERS UNDER A CONSTANT APPLIED PRESSURE.** A theoretical study on the compaction of metal powders under a constant applied pressure in terms of rheology is presented. The relationship between the stress and strain is described by using a nonlinear visco-elastic equation. The rheologic parameters of Sn, Cu, Fe and Mo powders are calculated by an electronic computer. The calculation result shows that theoretical and experimental data are in satisfactory agreement. (Edited author abstract) In Chinese. 8 refs.

**084344 OPTIMISATION OF THE COMPACTING**

**PROCESS OF P/M PRODUCTS.** The author considers parameters for the compaction process and the compact. Filling conditions and the compaction process of press and tool must be well reproducible in large quantity production runs. It is for this reason that there is a trend in press engineering - particularly for components of intricate shape - towards controlled movements. Recently this has resulted in presses with up to 7 axes of movements, including the controlled filling movement.

Fischer, E. (Dorst Maschinen & Anlagenbau, Kochel a See, West Ger). *Powder Metall Int* v 20 n 2 Apr 1988 p 27-30.

**084345 IMPROVED METHOD FOR SHOCK CONSOLIDATION OF POWDERS.** This technique uses a potential geometry with two co-axial tubes. The powder is contained in the internal tube. The external tube is surrounded by the explosive charge which is detonated at one end. This tube acts as a layer tube, impacting the internal tube. This technique generates pressures in the powder that can be several times higher than generated by the single-tube technique. The lower reaction velocity explosives minimize cracking of compacts. Improvements in compact quality were obtained in nickel-base superalloys, titanium alloys and aluminium-lithium alloys. (Edited author abstract) 25 refs.

**084347 ADVANCES IN COMPACTING PRESS TECHNOLOGY.** The Stokes Summit series compacting press has been designed to give the PM industry the capability of producing optimum parts, while at the same time reducing scrap and down-time. Especially with today's emphasis on just-in-time manufacturing and documentation through statistical process control, the 'Summit' press can meet the demanding standards required by customers. Edward F. Adolf of Pennwalt Corporation's Sharples-Stokes Division, in Warminster, PA, outlines in the following article some of the advances his company has made in powder compacting technology. Today's parts producers have a marked advantage over their predecessors of as recently as five to ten years ago, with the application of electronics and microprocessor technology to the art of pressing. Advances in automation, monitoring, and control have kept the powder metal compacting process a viable, economical alternative to other forming technologies. In order to remain competitive, the parts fabricators must take advantage of these advances in press design by investing for tomorrow.

Adolf, Edward F. (Pennwalt Corp, Warminster, PA, USA). *Met Powder Rep* v 42 n 9 Sep 1987 p 629-631.

**084348 VACUUM ASSISTED COMPACTING.** Juan A. Bas and Cesar Molins of Ames SA, Barcelona, Spain, describe a newly developed and patented process 'Vacuum Assisted Compacting', which provides a considerable increase in productivity in the compacting of PM parts. The process is said to be particularly suitable for the production of thin-walled components. After the tests performed, the 'Vacuum Assisted Compacting' (VAC) system is a technique of interest for PM, making it possible to increase the compacting speed and also the compacting of thin walled parts, and it facilitates the filling of chambers with poor flowing powders. 2 refs.

**084349 POWDER TRANSFER SYSTEMS IN PM COMPACTING.** Powder transfer is the controlled movement of metal powder from the fill position onto a transferred position which is relative to its final structural shape, and this movement of powder must be performed prior to any precompaction of the material taking place. John Reid of High Wycombe, Bucks, describes in detail the way in which powder transfer systems can be applied using four complex PM components as example. This article will describe in detail the way in which powder transfer systems should be applied, using four components shown in Figs 1 to 4, which are a fair representation of the PM parts normally requiring effective powder transfer. For those experienced engineers who require assistance in the manufacture of specific components which their companies are currently producing, or about to start the manufacture of, then further information is available having first agreed the terms of disclosure.

Reid, John (PM Industry, High Wycombe, Engl). *Met Powder Rep* v 42 n 9 Sep 1987 p 634-637.

**084350 SYSTEM FOR MEASUREMENT AND CONTROL OF PRESSING PARAMETERS.** This paper by R. Jansson and P. Samuelson of AB Sandvik Hard Materials, Stockholm, Sweden, describes a system for supervising and controlling the essential pressing parameters of mechanical powder compacting presses. The system is designed for monitoring the entire cycle of the pressing forces and correcting the compact weight to its target values. The adjustment of weights is optimized for the specific press tool and powder by means of an automatic pressure-weight calibration routine. The paper concludes with some ideas on how the information received by this system can be used for trouble-shooting purposes. A Sandvik system for the measurement of compaction forces and control of compacts weight has been described. Compared with a manual system, the automatic control system reduces the variations of compact weight by 20-50%. It also provides for a tool for trouble-shooting and tuning purposes. The highly automated operations allow non-specialists to operate the system. 3 refs.

## Computer Aided Analysis

**084351 OPERATOR-FREE POWDER COMPACTING.** The majority of all PM products today are produced by the so-called conventional die compaction process, and it is expected that this will continue in the immediate future. However, powder press utilization is often poor, and Ove Wigren of Convey Technik AB, in Harnosand, Sweden, describes the development of an operator-free 'Result' hydraulic press system where all the main functions are controlled by a combination of robotic devices and microprocessors. The above combination makes it possible to make powder compacts operator-free during part of a shift or a complete shift. The built-in flexibility means that the press changes the depth of fill for each stroke or after a desired number of compacts in order to stay inside the preset tolerances. Because the press station does not need the operator it is possible to increase the utilization up to 75-80% and reduce the number of operators by at least 50%.

**084352 MECHANISM OF THE CATHODIC PROCESS IN THE FORMATION OF A POWDER COPPER DEPOSIT.** As a result of earlier studies of the process of copper powder deposition in a microcell, conclusions have been drawn concerning the character of the electrocrystallization of dendritic deposits. The present work was undertaken with the aim of investigating the differences in copper electrocrystallization conditions at different cathode heights. A study was made of the variation of copper (II) ion and sulfuric acid concentrations inside the powder deposit over the rod cathode height. Experiments were conducted in a box-type electrolysis cell. 2 refs.

**084353 EFFECT OF PRESSING AND SINTERING CONDITIONS ON ANISOTROPIC SWELLING OF ELECTROLYTIC COPPER POWDER COMPACT.** The swelling of cylindrical compacts was measured after pressing at 2-8 t/cm<sup>2</sup> (196-784 MPa), after dewaxing at 500°C (773 K) for 30 min, and after sintering at 900°C (1173 K) for 5-180 Min. Compacts pressed under higher pressures (588-784 MPa) swelled during sintering, while those pressed under lower pressures (196-392 MPa) shrank. Both the swelling and the shrinkage of compacts pressed with die wall lubrication and sintered in cracked ammonia gas were larger than those of compacts pressed with powder lubrication or sintered in argon gas. The sintering time for the swelling of electrolytic powder compacts in argon gas was longer than that of compacts sintered in cracked ammonia gas or of compacts made from atomized powder. (Edited author abstract) In Japanese. 11 refs.

**084354 INFLUENCE OF ADDITIONAL Al<sub>2</sub>O<sub>3</sub> POWDER ON SINTERING BEHAVIOR OF CU ULTRAFINE POWDER.** The relative density and average Cu grain size of a sintered compact prepared from Cu ultrafine powder and Al<sub>2</sub>O<sub>3</sub> powders were investigated in relation to density and the amount and particle size of Al<sub>2</sub>O<sub>3</sub> powder. The compacts were sintered at 1273 K for 3.6 ks in hydrogen. Density increased with increasing amount of Al<sub>2</sub>O<sub>3</sub> powder. When the amount of Al<sub>2</sub>O<sub>3</sub> was larger than a limiting value, the sintered compact became porous. The grain growth of the Cu matrix became more suppressed as the Al<sub>2</sub>O<sub>3</sub> powder became larger in amount and finer in size. (Edited author abstract) In Japanese. 7 refs.

**084355 PREPARATION AND PROPERTIES OF DISPERSION STRENGTHENED Cu-Al<sub>2</sub>O<sub>3</sub> POWDER USING Al-ALOXIDE.** Cu-Al<sub>2</sub>O<sub>3</sub> powders were prepared by a process where electrolytic fine copper powders were mechanically alloyed with Al propoxide in air or argon then heated in hydrogen. The properties of the powders obtained were studied. The mass transfer of copper to the surface of each powder particle occurred at about 873 K. By this phenomenon, sinterability was improved. The powder processed in air was superior in sinterability and mechanical properties. (Edited author abstract) In Japanese. 10 refs.

**084357 MECHANICAL AND ELECTRICAL PROPERTIES OF PM BRASS.** Non-ferrous copper-base powders have been used for structural part applications for many years. Brasses and other prealloyed copper-base alloy powders are normally compacted within the 30 to 40 ton per square inch range resulting in the attainment of densities adequate for medium strength and hardness applications. The article discusses the production and properties that can be achieved with sintered brass. 2 refs.

Anon. *Met Powder Rep* v 43 n 1 Jan 1988 p 31-32.

**084358 RESEARCH OF P/M Cu-Al<sub>2</sub>O<sub>3</sub> ALLOY WORK-HARDENING BEHAVIOUR.** This paper deals with the work-hardening behaviour of a Cu-Al<sub>2</sub>O<sub>3</sub> alloy rod in the cold-worked and annealed states. The P-ΔL curve obtained on an electrical tension test device was reported. The work-hardening exponent was measured by using the first work-hardening curve and it was compared with the deformation resistance method. Results show that as the strain rate increases, the work-hardening degree and yield strength become larger, and both properties are affected by the chemical composition. (Edited author abstract) 6 refs. In Chinese.

**084359 RELATION BETWEEN SINTERABILITY AND INITIAL PACKING DENSITY IN LOOSELY SINTERED COPPER SPHERE COMPACTS.** Spherical copper powders with various initial packing densities were pressureless formed and sintered. Sintered properties, shrinkage, electrical resistivity, and breaking strength were measured and examined on the basis of simple geometrical model. These properties were dependent on the initial packing density of the green compact. Sintering shrinkage and breaking strength increased with increasing initial packing density whereas electrical resistivity decreased. The activation energy of the sintering process was 172.6 kJ mol<sup>-1</sup> and volume diffusion from the grain boundaries appeared to be the most plausible mechanism for sintering. (Edited author abstract) 8 refs.

**084360 COMPLETE DENSIFICATION OF COPPER SINTERED COMPACT BY THE ADDITION OF IRON POWDER.** The relative density (D<sub>r</sub>) of the sintered compact from water-atomized Cu powder was investigated in relation to the relative density (D<sub>g</sub>) of the green compact with the additions of iron powder. The green compact was sintered in flowing H<sub>2</sub> gas at 773-1253 K for 3.6-72 ks. D<sub>r</sub> tended to show a maximum of 93-96% and did not become 100% irrespective of the value of D<sub>g</sub> and sintering conditions. This finding is due to H<sub>2</sub>O gas produced by the reaction of a minute amount of retained copper oxide or dissolved oxygen. (Edited author abstract) In Japanese. 5 refs.

**084361 ELECTROCHEMICAL DISSOLUTION OF COPPER-IRON SULFIDES IN SULFATE AND SULFATE-CHLORIDE ELECTROLYTES.** The electrolysis of copper-iron mattes makes it possible, in one operation, to obtain copper powder meeting the requirements for PM powder. The problem discussed is determining an expedient ratio of copper and iron in mattes and optimizing the electrolyte concentration. It is most expedient to subject copper-iron mattes containing 30-40% copper to electrochemical dissolution. The optimum electrolyte acidity for obtaining copper powder is 30 g/liter  $H_2SO_4$  with a chloride ion content of 40 g/liter (for mattes with a copper content of 40-43%, the content should be 50-60 g/liter). 5 refs.

**084362 REVIEW OF RECENT DEVELOPMENTS IN POWDER METALLURGY OF COPPER ALLOYS.** Research aimed at improving the density and electrical conductivity, and the uniformity of these properties, in a relatively thick pressed and sintered pure copper parts for electrical applications is first described. Improved high-strength, high-conductivity copper alloys by rapid solidification powder metallurgy (RS P/M) processing has been an active area of investigation. Results from several studies are reviewed and discussed. The results of one investigation of spray forming as an RS P/M technique is reviewed. Powder metallurgy copper alloys that combine precipitation hardening and oxide dispersion strengthening have shown promise for applications where high temperature properties are important. Certain copper alloys incorporating oxide dispersoids have shown particular promise in maintaining mechanical properties and showing very low swelling after exposure to substantial neutron irradiation. (Edited author abstract) 15 refs.

**084364 EFFECT OF PRESSING PRESSURE AND SINTERING TEMPERATURE ON THE ELECTRICAL CONDUCTIVITY AND LINEAR ELONGATION OF COPPER POWDER SINTERED COMPOSITES.** The relationship between the electrical resistance and linear elongation and the parameters of pressing and sintering of copper powder materials is presented. From comparison of the changes in resistivity and the dilatometric curves it follows that three stages occur in the process of sintering. The value of electrical resistance shows a drop only for certain value of pressing pressure and sintering temperature. The specimens pressed under a pressure of over 190 MPa and sintered above 700°C show an increase in resistance and a decrease in conductivity. (Edited author abstract) 19 refs.

**084367 CHANGES IN THE LONGITUDINAL FLOW AND APPARENT PLASTIC POISSON'S RATIO OF A POROUS METAL STRIP DURING HOT DENSIFICATION ROLLING.** Analytical relationships between the longitudinal flow and the thickness deformation and between the apparent plastic Poisson's ratio and the relative density of a porous metal strip during hot rolling have been derived from geometrical considerations. Experimental data obtained from the hot rolling of porous copper strips of relative density of 0.4 agree well with the results predicted from analytical relationships. Changes in the longitudinal flow and the apparent plastic Poisson's ratio take place in three stages of densification. Stage I, densification up to the relative density of 0.70, involves densification by decreasing the pore channel widths without closing them. Stage II, densification from the relative density from 0.70 to that of 0.95, is associated with the patching of pore channels at some points, the number of which increases as the thickness deformation given to the strip increases. Stage III, densification of the strip from the relative density of 0.95 and onward, involves elimination of the newly formed closed porosity by shearing. (Edited author abstract) 8 refs.

**084368 EVALUATION OF ACTIVATION ENERGY IN SINTERED SAMPLES.** The neck curvature obtained in sintering two spherical copper particles is related to the neck radius of the contact area and the radius of the particles. The radius of the neck curvature, when expressed in terms of the fractional shrinkage, leads to method of evaluating the activation energy corresponding to the operating mechanism at different stages of sintering. The calculated values of activation energy confirm the diffusion mechanisms operative at different temperatures and different sintering durations. (Author abstract) 8 refs.

**084369 NOVEL PROCESS DEVELOPED FOR ULTRA-FINE METAL POWDERS.** A new technique which offers simple continuous production of submicronic metal powders has been developed by L'Air Liquide of France. The process involves melting the metal to be converted into powder in a superheated bath under a pressure greater than 1,000 Pa. This superheated metal is then covered with a cryogenic liquid and fumes are emitted which consist of spherical metal particles generated by condensation of metallic vapours in the gas film separating the cryogenic liquid from the molten metal. The particles are then carried away by the flow resulting from the liquid film vapourisation. To date L'Air Liquide has produced powders of copper, silver, zinc and magnesium.

## Copper Graphite

**084370 INFLUENCE OF POROSITY AND SLIDING RATE ON THE TRIBOTECHNICAL PROPERTIES AND FEATURES OF DEFORMATION ON THE SURFACE LAYERS OF COPPER-GRAPHITE MATERIALS DURING FRICTION WITHOUT LUBRICATION.** The relationship of the intensity of wear of a copper-graphite material containing 10% graphite to porosity has an extreme character. The optimum antifriction properties are obtained with a porosity of 6-12%. In this interval of porosities the minimum degree of deformation of the surface layer in friction is observed. The minimum values of the intensity of wear and the coefficient of friction are observed in the 2.6-22 m/sec range of sliding rates, at which solid films of secondary structures distinguished by low roughness are formed on the surface. 11 refs.

## Copper Iron Alloys

**084371 EFFECT OF SINTERING TEMPERATURE AND PRESSURE ON SINTERED AND FRICTION PROPERTIES OF A Cu BASE FRICTION MATERIAL.** A powder mixture of 71 Cu-12Fe-10C-4SiO<sub>2</sub>-2Pb-0.5MoS<sub>2</sub> (in mass%) has been compacted into disks. The pellets and steel backing plates have been diffusion bonded and sintered at various temperatures (700 to 965°C) and pressures (1.5 to 3 MPa). Under constant pressure, porosity decreases and sintered hardness increases with increasing sintering temperature. A change in porosity and hardness is observed by raising the temperature from 950 to 985°C. A gradual increase of sintered density and hardness with sintering pressure has been observed. As sintered hardness increases, friction coefficient and wear rate decreases slightly. (Edited author abstract) 10 refs.

Kim, J.W. (Korea Advanced Inst of Science and Technology, Seoul, South Korea); Kang, B.S.; Kang, S.S.; Kang, S.-J.L. *Powder Metall Int* v 20 n 3 May 1988 p 32-34.

## Copper Nickel

**084372 PM WROUGHT CuNiSn STRIP FINDS APPLICATION IN THE ELECTRONICS INDUSTRY.** Cu-Ni-Sn alloys made by powder rolling and sintering are attractive materials for use in the electronics industry, particularly when high spring strength, good formability, electrical conductivity and corrosion resistance are required. Pfinodal alloy strip is a product of Pfizer's patented wrought PM technology. In this process strip is made by cold compaction of fully homogenized high purity powder which has been produced by melting and atomizing high purity copper, nickel and tin. The molten alloy stream is broken into fine homogeneous particles by high pressure water jets. The atomized powder is then fed between horizontal rolls and friction between the powder and the roll surface draws the powder into the roll gap where the roll pressure produces a mechanical bond between the powder particles. After compaction the green strip is sintered, coiled and passed through a series of high temperature anneals and cold rolling steps to produce 100% density.

Anon. *Met Powder Rep* v 43 n 1 Jan 1988 p 33-34.

## Copper Nickel Tin

**084373 SMALL ANGLE X-RAY SCATTERING STUDY OF THE DECOMPOSITION PROCESS OF THE POWDER METALLURGY ALLOY Cu-15wt%Ni-8wt%Sn.** The authors studied an alloy named Pfinodal using SAS. Whereas fluctuations of the tin composition are present at the very beginning of the decomposition process, such fluctuations are not in agreement with the SAS measurements. The anomalous effect considers that scattered entities having the composition (Cu<sub>0.75</sub>Ni<sub>0.25</sub>)<sub>3</sub>Sn are responsible for the opposite

intensity variations near both Ni and Cu K-edges. This technique of anomalous small angle X-ray scattering is a concrete example in a ternary alloy for differentiating between different models which can fit the classical data. 11 refs.

#### Copper Niobium

**084374 THEORETICAL AND EXPERIMENTAL INVESTIGATION OF THE PROCESS OF PLASTIC DEFORMATION OF SINTERED COMPOSITE MATERIALS. II. EFFECT OF SHAPE OF HARD INCLUSIONS ON THE DEVELOPMENT OF SIMULTANEOUS DEFORMATION OF THE PHASES OF A COMPOSITE MATERIAL.** When the strength characteristics of the soft and hard phase materials of a given composite material and certain parameters are known, it is possible to determine minimum values of the parameter  $t/d$  (shape factor) at which simultaneous deformation of the two phases of the material will commence under any given conditions of deformation. To verify the findings of a theoretical investigation, experiments were carried out in which a composite material of the copper-40% niobium system was rolled. As hard inclusions chopped lengths of niobium wire with  $t/d$  ratios of 2, 5, and 10 were used, the reduction in each stage of deformation being 15%. The results show the variation of the degree of deformation of the inclusions with deformation. 5 refs.

Kiparisov, S.S. (Moscow Inst of Fine Chemical Technology, USSR); Kiyanskii, I.A.; Perel'man, V.E. *Sov Powder Metall Met Ceram* v 26 n 9 Sep 1987 p 697-701.

**084375 USE OF THE ROTATING-ELECTRODE PROCESS IN THE FABRICATION OF Cu-Nb COMPOSITES.** Extremely fine niobium dendrites can be attained by rapid solidification of Cu-Nb alloys. The rotating electrode process (REP) is a powder atomization technique with cooling rates on the order of  $10^3$  to  $10^4$  °C sec<sup>-1</sup>. These cooling rates are predicted to yield niobium dendrites of diameter 1.4 to 3.0 μm. In addition, the REP uses no crucible and the melting is done in an inert environment which makes it an attractive process for reactive metals like niobium. The powders did not exhibit increased tensile strength upon deformation due to the non-uniform microstructure. 14 refs.

#### Copper Niobium Alloys

**084376 THEORETICAL AND EXPERIMENTAL INVESTIGATION OF THE PROCESS OF PLASTIC DEFORMATION OF SINTERED COMPOSITE MATERIALS. I. ANALYSIS OF THE CONDITIONS OF SIMULTANEOUS DEFORMATION OF THE DIFFERENT PHASES OF A COMPOSITE MATERIAL.** The article presents the results of an investigation into the dependence of the shear strength of composite materials on the magnitude of the compressive stress. Experiments were carried out on nonporous composite materials from powders of ductile metals (copper and aluminum) and a hard filler (niobium and alumina) and on porous blanks (compacts) pressed from the powders. The filler content varied from 10 to 70% and the porosity of the compacts, from 60 to 10%. Curves of shear strength vs compressive stress (plasticity function of the materials) are shown for porous compacts and for dense composite materials of the copper-niobium system. It was found that the plasticity function of a composite material (like that of a porous powder medium) depends on the first invariant of the stress tensor. The intensity of this dependence, assessed by the internal friction angle, is determined by the magnitude of the difference in strength properties between the components of the composite material, the area of the property discontinuity surfaces in unit volume of the

composite, and the relative orientation of the property discontinuity and slip surfaces. 6 refs.

#### Copper Tin

**084377 INVESTIGATION OF PORE SIZE DISTRIBUTION IN POROUS POWDER MATERIALS BY DIFFERENT METHODS.** The interest in methods of investigating specific properties of porous power materials (PPM) is due to their application in filters, catalysts, flame barriers, mixers, capillary structures of heat pipes, etc. An important characteristic of PPM determining their operational properties is the power size distribution. Most widely used are three methods of investigating pore size distribution: mercury porosimetry, substitution of liquid in pores by gas and metallography. The article compares these methods in measurements on bronze powder. 8 refs.

**084378 DENSIFICATION KINETICS OF A COPPER-TIN POWDER COMPOSITE DURING ELECTRIC-DISCHARGE SINTERING.** The density of specimens produced by electric discharge sintering depends to a large extent on the mechanical and electrical parameters of the process. In the electric discharge sintering of a copper-tin composite, raising the prepressing pressure from 4.17 to 12.5 MPa decreased the extent and rate of shrinkage by more than half. To attain the same hardness on passing from a low (4.17 MPa) to a higher prepressing pressure (12.5 MPa), it was necessary to increase the current density by 100 A/cm<sup>2</sup> (from 595 to 695 A/cm<sup>2</sup>). 4 refs.

**084379 HYDROMETALLURGICAL PROCESS FOR PREPARING COMPOSITE Cu-Sn POWDER.** The present work has tried successfully to cement the copper-tin composite powders from sulfate solutions of Cu and Sn at pH 0.12 to 1.2%. The composite powders with copper compositions of 91.2% and 79.9% were obtained, respectively, for the theoretical corresponding compositions of 90% and 80%. Thus cemented higher copper content powders are of cubic shape, while increasing contents of tin tends to distort the cubic shape. The rate of copper cementation is enhanced by the increasing pH values of the initial solution. (Author abstract) 6 refs.

**084380 DYNAMICS OF INTERPARTICLE REACTIONS IN SPHERICAL METAL POWDERS DURING ELECTRIC SINTERING.** A study was made of atomized powder particles of BrOf-10-1 tin bronze. The dynamic characteristics of interparticle neck formation depend not only on current density (raising the current density by 1.7 times increases interaction rates by an order) but also on the positions of the particles relative to the direction of passage of current (particles lying in a plane parallel to the direction of passage of current interact 3.4-5 times more rapidly than particles lying in a plane perpendicular to this direction). The kinetics of powder particle sintering by an electric current is due to the most intense sintering mechanisms such as viscous flow, transport through the gaseous phase, and spreading of liquid metal over the solid surfaces of particles. The strongest influence on the kinetics of mutual particle sintering is exerted by a transport mechanism. 7 refs.

#### Costs See Also COMPOSITE MATERIALS—Mechanical Properties; INDUSTRIAL ECONOMICS.

**084382 COST MODELING RS POWDERS PRODUCED BY INERT GAS ATOMIZATION.** In order to understand the major factors affecting the manufacturing costs of rapidly solidified powder metals (RSPM), economic models have been developed taking into consideration industrial processes and RSPM research. The gas atomization model used in this study was developed to be user-interactive. It was created on a Lotus 123 spreadsheet which allows it to be run on IBM PC's or compatibles. The model is divided into three sections: inputs, cost calculations by unit operation, and results. Using these components, the model allows the user to review the effects of one or several process variables on the overall costs. 15 refs.

**084385 CONSOLIDATION BY ATMOSPHERIC PRESSURE IN GLASS MOULDS GIVES HIGH DENSITY PREFORMS.** Atomized powder is loaded into glass molds which are evacuated and the resulting mold/compact is sintered at atmospheric pressure. Resulting preforms are said to be 98-99% of theoretical density. Cytemp Specialty Steel Division, Cyclops Corporation, has developed an alternative PM consolidation process, Consolidation by Atmospheric Pressure (CAP), which is said to combine all of the inherent advantages of PM with several others, including increased cleanliness, greater flexibility, easier fabricating and machining characteristics, and improved hot working and heat treating characteristics. US Patent No 4,227,927 uses standard melting and atomization methods to make powder. After being screened to customer-specified mesh size, the powder is loaded into a blender/drier, where it is mixed and chemically treated with an additive in a carrier solution such as methanol. The chemical additive, which promotes diffusion bonding during subsequent consolidation, varies with different types of specialty steels, but is a normal constituent of the alloy. During the vacuum drying cycle, the methanol evaporates, leaving a minute coating of the chemical additive on all powder particle surfaces.

Anon (Cytemp Specialty Steel Div, Bridgeville, PA, USA). *Steel Times* v 215 n 10 Oct 1987 p 516.

**084386 ISOSTATIC PRESSING EXTENDS POWDER METALLURGY PERFORMANCE.** Isostatic pressing of powder metallurgy components removes the inherent problem of density gradients which are unavoidable with conventional press tools. In the case of hot isostatic pressing densities of up to 100% can be reached. The IMT Division of National Forge specializes in applying HIP technology to modern materials. More than 15 HIP units located in the USA and in Belgium can offer industry the service it needs, particularly in the fields of tool steel, stainless steel, powder metallurgy, casting densification, diffusion bonding, and HIP processing of ceramic materials. National Forge has been building HIP units for the PM and ceramic industry since the early development of the process. Units ranging from 90mm diameter for laboratory units to 1500mm for production units operating at temperatures up to 2200°C and pressures to 4000 bar are built for many specific applications.

Anon (Natl Forge Europe, Sint-Niklass, Belg). *Steel Times* v 215 n 10 Oct 1987 p 518.

**084387 PRODUCTION OF SOME METAL POWDERS BY THE ROTATING ELECTRODE PROCESS.** The Rotating Electrode Process is a method for producing spherical metal powder particles by melting the end of the metal rod which is rotated at high speed about its longitudinal axis. Molten droplets are centrifugally ejected and chilled into solid form in an inert gas atmosphere or in a vacuum. The characteristics of Rotating Electrode Process powder are a spherical shape with very few irregular particles by a ceramic free process, the maximum yield of powder within a very narrow size range by rotational speed control and ideal consistent and reproducible flow rate and apparent density for pressing and sintering process. (Edited author abstract) 8 refs.

**084388 NUMERICAL SIMULATION OF HIP PROCESS.** A numerical simulation method based on viscoplastic theory is introduced to simulate the densification behavior of metal powder during the hot isostatic pressing process. The dependence of flow stress on temperature, strain rate and relative density of the material was taken into consideration. Uniaxial compression tests were carried out to determine the parameters of the constitutive equations. Experimental results for a turbine disk confirmed the accuracy of this simulation technique. (Author abstract) In Japanese. 3 refs.

**084389 ON DENSIFICATION AND SHAPE CHANGE DURING HOT ISOSTATIC PRESSING.** When the temperature of a powder compact is raised, heat diffuses inwards from the surface. If the compact is under pressure (as it is during HIPing), the surface layers start to densify, increasing the local thermal conductivity. Under certain conditions a densification front propagates into the powder, and this leads to changes of shape of the compact which is no longer identical to the preform shape. The conditions which lead to non-uniform densification are analyzed and the consequences are compared with experiments on copper, alumina and tool steel. (Edited author abstract) 12 refs.

**084390 COMPUTER MODEL FOR PREDICTING DENSIFICATION IN POWDER FORGING.** One method of obtaining the information required concerning the deformation behaviour of aluminium alloys during forging is to use modelling techniques. The Centre de Mise en Forme des Matériaux of the Ecole des Mines in Paris has developed a computer program which permits modelling of the hot forging process approached through a yield criterion adapted to porous material plastic deformation. The program describes both densification and plastic flow by relating the equivalent stress supported by the material to the stress deviator and stress tensor functions through rheological parameter functions of relative density and temperature. The forming process simulation is based on a finite element calculation.

**084391 MODELLING SHAPE CHANGE OF PARTS PRODUCED BY HOT ISOSTATIC PRESSING OF POWDERS.** Models for analysing shape changes during the HIPping of powder compacts enclosed in preshaped containers are presented. Two limiting mechanisms are considered: homogeneous densification and the motion of a sharply defined densification front through the compact as HIPping proceeds. The shape changes and shrinkages occurring in a number of simple one, two, and three dimensional shapes are analysed and illustrated. Although some of the assumptions implicit in the model are at variance with the conditions found in practice, it is concluded that useful insights are provided into the shape changes occurring during HIPping. ## Diffusion

**084393 INFLUENCE OF POROSITY ON MUTUAL DIFFUSION IN POWDER MATERIALS.** If the method of obtaining the material is such that the length of the diffusion zones are greater than the size of the pores and the distance between them, as experiments on the diffusion pairs showed, then the effective coefficient of mutual diffusion depends both upon the total porosity and

upon the size of the pores. If the diffusion zones are on the order of or less than the distance between the pores, as occurred in the homogenization tests, then only the defectiveness of the crystalline lattice but not the porosity of the material may influence the effective coefficient of mutual diffusion. To verify this conclusion an investigation was made of the mutual diffusion in the Fe-Ni, Fe-Cr, and Cr-Ni diffusion pairs prepared by pressing of powders and by the method of drying of a suspension, which provides a higher porosity and larger pores in them than in parts obtained by pressing. 6 refs.

## Economics

**084395 ASPEKTE DER PULVERMETALLURGIE HOCHFESTER LEICHTMETALLEGIERUNGEN AUF ALUMINIUM- UND TITANBASIS.** [Aspects of the Powder Metallurgy of High-Strength Light-Metal Alloys Based on Aluminum and Titanium]. Attempts have been made over a ten-year period to apply the advantages expected from powder metallurgy - cost reduction, improvement of properties and development of new alloys not producible by conventional ingot metallurgy - to high-strength lightweight alloys. State of the art and problems still to be solved are reviewed with respect to the particular objectives, and future trends of development are pointed out. For aluminum alloys, the main objective is the improvement of properties, e.g., higher elevated-temperature strength by rapid solidification and mechanical alloying, whereas in the case of titanium alloys emphasis is on the lowering of production costs. Meanwhile, improved properties could be achieved by rapid solidification for titanium alloys as well. But, the improvement of profitability still remains an important task to be solved for both types of alloys. (Edited author abstract) In German. 23 refs.

## Finland

**084404 FINLAND.** In spite of a small population, Finland has strong ferrous and non-ferrous metallurgical and mechanical working industries. The industrial activities in the powder-metallurgical field have been limited to the production of fine cobalt powder and cemented carbide parts. A substantial amount of fundamental and applied research has been carried out in the P/M field during the last 20 years, mainly at Finnish technical universities and research institutes. The research efforts related to powder metallurgy have been enhanced during 1987 due to the start of an extensive research program. These projects are oriented towards the development of P/M process technologies and powder metallurgical materials. New applications for powder metallurgical techniques are also being studied.

Grinder, N. Olle (P/M Technology AB, Nynashamn, Sweden); Sirkkola, Erkki M. *Int J Powder Metall (Princeton NJ)* v 24 n 2 Apr 1988 p 135-138.

Graphite Compounds See ELECTRIC CONTACTS—Manufacture.

## India

**084405 POWDER METALLURGY IN INDIA.** The status of the P/M industry in India is assessed. There has been recent growth in the areas of ferrous powder production, hard metals, and structural P/M parts. The latter area is illustrated by reference to the automotive industry and the sales of two, three and four-wheel vehicles. Current R&D activities are highlighted and a brief review is given of P/M education and professional society activities. (Author abstract).

## Injection Molding

**084406 RHEOLOGY OF METAL INJECTION MOLDING FEEDSTOCK.** In this paper the features of the MIM process in general are reviewed and the rheological characteristics of the plastic binder will be examined. The rheological characteristics will also be interpreted to qualitatively predict the flow behavior in injection molding. This paper represents the initial studies in a long term project aimed at optimizing the metal injection molding process. 12 refs.

Shah, J. (Univ of Lowell, Lowell, MA, USA); Nunn, R.E. *Powder Metall Int* v 19 n 6 Nov 1987 p 38-40.

**084407 PRESENT STATUS OF P/M INJECTION MOLDING (MIM) - AN OVERVIEW.** The current technologies for metal injection molding (MIM) are reviewed. The factors affecting the growth of the industry are summarized and compared. This leads to estimates of the cost of making MIM parts, how they compare with investment castings, and a forecast for future market growth. The present markets, shipments, tooling, technology, and history of the 29 active MIM procedures in

North America and Europe are reviewed by company. A table contains mechanical property data for MIM materials. Work under way at research institutions and efforts at standardization are described. (Edited author abstract)

Pease, Leander F. III (Powder-Tech Associates Inc, North Andover, MA, USA). *Carbide Tool J* v 20 n 1 Jan-Feb 1988 p 4-15.

**084408 DEVELOPMENTS IN SINTERING INJECTION-MOLDED P/M PARTS.** Small metal parts of intricate shape can be made by injection molding. Metal powders are mixed with plastic binder materials. Following molding, the binder is removed from the matrix and the powder is sintered to form the final article. Excellent repeatability hence close mechanical tolerances are practical. This technique for manufacturing has been proved to be cost effective for the production of a wide range of parts which otherwise would need to be made by more expensive lost wax casting, machining, or assembly of a number of small pieces. However, the utility of the process has been limited and a reduction in both the material cost and the processing cost is desirable. The injectavac furnaces are one of the developments which lower the cost of this process.

**084409 PULVERMETALLURGISCHE SPRITZGIESSEN - EIN NEUES FORMGEBUNGSAUSFAHREN FUER SINTERTEILE KOMPLIZIERTER GESTALT.** [Powered Metal Injection Molding - New Forming Techniques for Sintered Complex Shapes]. An overview of the current manufacturing technology that combines powder metallurgy and plastic molding methods for complex parts is given. The advantages of powder metallurgy over other manufacturing methods are pointed out. 6 refs. In German.

Lange, E.; Poniatowski, M. *Konstruktion (Berlin)* v 40 n 6 Jun 1988 p 233-238.

**084410 INJECTION MOULDING OF POWDERS.** Different types of iron powder possessing a range of particle characteristics and a standard grade of hardmetal powder have been mixed with low molecular weight thermoplastics and wax formulations to produce plastisols suitable for injection moulding. Mixing of up to 70 vol.-percent loading of powder with waxes and low density polyethylene formulations has produced acceptable rheological requirements for the production of sound mouldings. Test shapes have been moulded on a conventional injection moulder and modified pressure die casting machine with multicavity moulds. Measured green densities were found to correspond to theoretical values. Debinding studies have been evaluated by thermogravimetric analysis and sintering profiles applied to produce relatively high densities in the test shapes. Final density levels were influenced by particle characteristics, mixing conditions, and debinding and sintering profiles. (Edited author abstract). 12 Refs.

**084412 COMPOSITION AND MAGNETIC PROPERTIES OF FINE IRON POWDERS TREATED WITH ORGANIC COMPOUNDS.** In this article are presented the results of an investigation into the composition and magnetic properties of iron VFPs modified with an organosilicon polymer (OSP) and also data yielded by an analysis, carried out by conversion Mossbauer spectroscopy (CMS), of the surface layers of particles with different coatings to depths of up to 0.1  $\mu\text{m}$ . The phase compositions of VFPs were analyzed by the absorption and conversion Mossbauer spectroscopy techniques and by x-ray diffraction (construction of diffractograms). CMS spectra were recorded at room temperature, using a flow-type proportional counter with a helium-methane filler. Electrons were registered having a kinetic energy corresponding to depths of layers investigated of up to 0.1  $\mu\text{m}$ . When, as in this case, specimens are studied in the form of powders whose particle size substantially exceeds the maximum departure depth of conversion electrons, relative areas under different CMS lines cannot provide unique information on the relative amounts of the corresponding iron-containing compounds represented in spectra. In such a case CMS spectra afforded information only on the qualitative composition of the surface of a specimen. In absorption spectra such a correspondence is observed. In our work the latter were processed on the computer to determine the relative amounts of the  $\alpha\text{-Fe}$  phase and various oxides. 7 refs.

**084413 EFFECTS OF MO AND CR CONTENTS ON THE PROPERTIES AND PHASE FORMATION OF IRON MOLYBDENUM BORIDE BASE HARD ALLOYS.** Fe-5B-xMo-yCr alloys with five levels of Mo contents which correspond to Mo/B atomic ratios ranging from 0.7 to 1.1 and three levels of Cr contents, namely 0.5 and 10 mass%, were prepared in order to investigate the effects of Mo and Cr contents on the mechanical properties and the phase formation in  $\text{Mo}_2\text{FeB}_2$  type complex boride base hard alloys. The best mechanical properties were obtained for the Fe-5B-xMo alloys when Mo was added to match the Mo/B atomic ratio of the alloys with that of  $\text{Mo}_2\text{FeB}_2$ . Similar results were noted for the Fe-5B-xMo-yCr alloys with optimum Mo/B ratios somewhat lower than unity. Metallographic studies revealed formation of third phases, such as  $\chi(\text{Fe}_3\text{CrMo})$ ,  $\text{M}_6\text{C}$ ,  $\text{Fe}_2\text{B}$  and  $\text{Cr}_2\text{B}$ , at compositions off the optimum Mo/B values. **084414 JOINING OF IRON POWDER COMPACTS BY AN INFILTRATION METHOD.** Joining of iron powder compacts by an infiltration method was attempted. The joining strength of the compacts was investigated with respect to variations in roughness of the surface, applied pressure, relative density of preforms, infiltration temperature and the time. The joining strength was found to be almost equal to those of monobloc compacts by conventional infiltration when the joining was done under the optimum conditions. Joining of the iron powder compact and wrought steel samples such as S10C and S55C was also carried out and high strength could be obtained by this method. Samples with complicated shapes or with holes in the parts could be easily made with the infiltration technique proposed. (Author abstract) 8 refs.

**084415 ROTARY FORGING OF METAL POWDERS.** This paper outlines the principles of operation of a nutation spin rotary forging machine and describes initial experiences of its application to the consolidation of metal powders. Seven different ferrous and non-ferrous powders were studied, including two aluminium alloys made by rapid solidification methods. Relative densities > 96% have been obtained with all materials. The forces required consist of two components. An initial, uniaxial compaction phase to densities of approximately 80-90% requires ordinary compaction forces. Final densification during a second, nutation, phase requires additional forces which are only 5-10% of the initial compaction force. Microstructures and hardness surveys on sections of compacts are presented and used as a basis to discuss possible mechanisms of densification and material deformation brought about by the process. (Author abstract) 5 refs.

**084416 CLOSE-COUPLED GAS ATOMISATION OF METAL ALLOYS.** A nozzle design that closely couples the atomising gas jet to the melt stream has been developed. Close-coupling allows more efficient use of the gas energy to create fine powder than do conventional designs. Yields of -37 micrometer powder of high surface tension alloys in excess of 75 wt.% have been attained at moderate gas consumption. Because of the relationship between reduced particle size and increased cooling rate, and the high yield of fine powder which is attainable with the nozzle, the close-coupled nozzle is an attractive method for producing rapidly solidified powder. Finally, high-speed photographic studies of the atomisation process show that melt stream disruption occurs right at the nozzle tip. The observed break-up process is not the same as that reported in the literature for conventional atomisation nozzle designs. 12 refs.

**084417 COMPACTIBILITY OF PARTIALLY DIFFUSION-ALLOYING IRON-BASED POWDERS AND THEIR HOMOGENEITY AFTER SINTERING.** Compactibility, homogeneity and mechanical properties, etc. of sintered specimens made from partially diffusion-alloying powders of Fe-1.5 Cu-2 Ni, Fe-7 MC and Fe-2 Cu-0.6 P (mixed with carbon respectively) have been studied. It demonstrates that partially diffusion-alloying powders possess superior compactibility as well as sintering homogeneity. After sintering distribution of copper, molybdenum and phosphorus etc. elements were very homogeneous. The strength of above three sintered materials is 500-600 and 700N/mm<sup>2</sup> respectively. **084418 PRODUCTION AND ALLOYING OF FERROUS POWDERS.** To avoid using very high compacting pressures which can lead to tool wear or tool breakage, it is important that the iron powder has a good compressibility. By carefully selecting the raw materials, by using modern steel refining techniques and by optimizing the powder annealing process it has been possible for the powder manufacturers to continuously increase the compressibility of both sponge and atomized iron powders while maintaining good green strength properties after compacting. By adhesive or diffusion bonding of the alloying elements, problems with segregation or dusting can be eliminated. Large scale production trials have shown that dimensional tolerances can be greatly improved using both these techniques. Finally the powder manufacturers can contribute in several ways to the joint effort to introduce PM parts into more highly stressed applications.

**084419 DEVELOPMENT OF THE PRODUCTION TECHNOLOGY FOR THE FERROUS SINTERED STRUCTURAL PARTS IN JAPAN.** This report explains the history of the development of ferrous sintered structural parts by illustrating the progress of their technology in Japan. The production technology includes the production equipment and the iron powders in addition to compacting and sintering. The production of ferrous sintered structural parts started with the introduction of foreign technology but since 1965, domestic technology has been fostered and the 1970s have seen expansion of the sintered parts market through the developments of Japanese technology. In the 1980s Japanese production technology of sintered parts reached a leading position in the world. (Edited author abstract) In Japanese. 6 refs.

**084420 ASSEMBLED CAMSHAFT FOR I.C. ENGINES WITH FORGED POWDER METAL CAMS.** An element in the automotive industry's efforts to improve fuel economy and engine performance is the introduction of roller tappets to reduce friction in valve trains. As a result, contact stresses in excess of 200,000 psi may be experienced at the roller and cam (shaft) interface. Conventional cast iron camshafts cannot effectively carry this stress level. After studying several alternatives, the authors have developed a camshaft with powder forged cam lobes. (Edited author abstract) 10 refs.

**084422 THERMOGRAPHIC STUDY OF THE OXIDATION PROCESS OF ULTRADISPERSED ELECTROLYTIC IRON POWDERS.** This report presents the results of investigation of the oxidation process of iron powders of two types: highly dispersed electrolytic powder designated PZhVE and PZh4K powder produced by reduction of scale and grinding in a planetary mill. Oxidation is accompanied by liberation of a significant quantity of heat as the result of the oxidation reaction. This leads to transformation of the metal powder into the oxide phase, sintering of the basic material, slowing of oxidation, and an increase in the effective activation energy of this process. 13 refs.

Zhigotskii, A.G. (Acad of Sciences of the Ukrainian SSR, USSR); Radoshinskaya, S.I.; Shvets, T.M. *Sov Powder Metall Met Ceram* v 26 n 5 May 1987 p 415-419.

**084423 PREPARATION OF Fe-, Co, AND Ni-BASED AMORPHOUS ALLOY POWDERS BY HIGH-PRESSURE GAS ATOMIZATION AND THEIR STRUCTURAL RELAXATION BEHAVIOR.** By using newly constructed high-pressure gas atomization equipment, the effect of atomizing gas (Ar, N<sub>2</sub>, or He) on the formation tendency of amorphous alloy powders and their Curie temperature ( $T_c$ ), structural relaxation, glass transition ( $T_g$ ), and crystallization ( $T_x$ ) was examined for Fe-P-C, Fe-Si-B, Fe-Cr-Mo-P-C, Co-Si-B, Ni-Si-B, Ni-Pd-P, and Cu-Zr alloys with easy glass forming capacity. Amorphous powders are formed in all the alloy

systems and the critical diameter for the formation of amorphous powders is 25 to 44  $\mu\text{m}$  for Ar and 44 to 100  $\mu\text{m}$  for He. The average particle size is smaller for He than for Ar and  $\text{N}_2$ . No appreciable differences in  $T_C$ ,  $T_B$ , and  $T_X$  of  $\text{Fe}_{77}\text{P}_{13}\text{C}_{10}$  amorphous powders with the kind of atomizing gas are seen and these values are the same as those of the amorphous ribbon with 20  $\mu\text{m}$  thickness. He atomized  $\text{Fe}_{77}\text{P}_{13}\text{C}_{10}$  powders exhibit a lower onset temperature of relaxation and larger heats of relaxation and crystallization as compared with the Ar- and  $\text{N}_2$ -atomized powders and the values of the He-atomized powders are comparable to those of the ribbon sample, indicating that He-gas atomization has a higher cooling capacity and results in the formation of a more disordered amorphous structure. This difference agrees with the tendency estimated under the assumption that heat removal from atomized droplets occurs by Newtonian cooling caused only by the convective heat transfer. Accordingly, the greater heat removal capacity of He gas is a dominant factor for the formation of amorphous alloy powders with more unrelaxed atomic configurations. (Edited author abstract) 18 refs.

**084424 CONTROLLED THERMAL EXPANSION METAL-CERAMIC COMPOSITES BY CO-SINTERING.** A two phase metal-ceramic composite composed of iron and cordierite was formed from powders using die compaction and sintering. Boron was added to induce co-sintering of the two phases. Thermal expansion was measured versus composition up to 80 vol.% cordierite. As the cordierite content increased, the thermal expansion decreased, with a dramatic decrease when the cordierite became a continuous phase. The thermal expansivities were compared with predictions from published models, but no model was found that adequately predicts the results over all compositions. The difficulty with modeling originates with the simplifications made in treating the connectivity of the two phases. The material may be used as a semiconductor substrate. (Edited author abstract) 22 refs.

**084425 EFFECT OF ZINC STEARATE ON THE PROPERTIES OF SINTERED PRODUCTS.** The authors studied  $\text{ZnGr}_0.8\text{D}_2\text{N}_1$  based on powdered iron marke PZh2M3. When a large amount of plasticizer is mixed with a metal powder, the plasticizer envelops the surface of the particles with a thick layer and clogs the open intraparticle pores. This impedes degassing of the charge in molding and thereby promotes the formation of closed pores filled with gas under high pressure and with the plasticizer itself. In the production of structural products from powder metallurgy materials, the optimal content of zinc stearate in the charge is 0.5-0.7%. A further increase (from 0.7 to 1.5%) increases total and open porosity and reduces closed porosity. Such a content of zinc stearate in the charge may be recommended for the production of bearings. 7 refs.

**084426 SINTERING MECHANISMS AND MECHANICAL PROPERTIES OF  $\text{Fe}_2\text{B}$  BASE HARD ALLOYS.** By utilizing the excellent properties of boride, a new type of sintered hard alloy has been developed. The sintering phenomena of  $\text{Fe}$ -(4-8) wt%  $\text{B}$ -(0-30) wt%  $\text{Cr}$ -0.3 wt%  $\text{C}$  alloys were studied by TG-DTA, dilatometric measurements and x-ray diffractometry. The mechanical properties of the sintered alloys are discussed. The alloy comprises an  $\text{Fe}_2\text{B}$  type boride as a hard phase and a ferrous binder phase containing Cr and C. When the hard alloy contains more than 10 wt% Cr, both  $\text{Fe}_2\text{B}$  and  $\text{Cr}_2\text{B}$  type borides coexist. The liquid phase sintering is attained by two liquid forming reactions, namely,  $\gamma\text{-Fe} + \text{Fe}_3(\text{B,C}) + \text{M}_{23}(\text{B,C})_6 \rightarrow \text{L}_1$  and  $\gamma\text{-Fe} + \text{Fe}_2\text{B} \rightarrow \text{L}_2$ , the

latter reaction occurring in a higher temperature range. (Edited author abstract) In Japanese. 11 refs.

**084427 MECHANISMS OF ADHESION AND DIFFUSION BONDING OF POWDERED ALLOY SHEET.** A powdered alloy sheet process which provides the required minimum wear resistant layer was developed. This layer was obtained by bonding a flexible sheet formed with wear resistant alloy powder using a polymer as the binder. After tests on alkyl resin, urethane polymer, vinyl acetate and acrylic resin, acrylic resin was selected for the binder due to superior properties for bonding. The sheeted powder of mixed SUS-410 and OS-23 with adding acrylic resin of 2-4 wt% was soft enough to bond to the curved parts by sintering after preheating. Cam shafts rocker arms and the swing arms were made by this process. (Edited author abstract) 3 refs. In Japanese.

**084428 DENSIFICATION AND GRAIN GROWTH OF IRON ULTRAFINE POWDER DURING PRESSURE-SINTERING.** A green compact was pressure sintered under 100 and 200 MPa at 673-973 K for 1.8 ks in flowing hydrogen. The nearly full densification temperatures under 100 and 200 MPa were lower by about 150 K and above 300 K respectively than that (970 K) in pressureless sintering. The minimum value of the average grain size in the dense pressure sintered compact was about 0.15  $\mu\text{m}$  which was smaller than 1.2  $\mu\text{m}$  of the pressureless sintered compact. The hardness of the pressure-sintered compact was as high as about 385 H<sub>v</sub>, compared with about 85 H<sub>v</sub> of the coarse grained metal. The Hall-Petch linear relationship between H<sub>v</sub> and the square root of the grain size was confirmed to hold also for the grain size range larger than about 0.15  $\mu\text{m}$ . (Edited author abstract) 20 refs.

**084429 SOME OBSERVATIONS ON HOT-FORGING CHARACTERISTICS OF IRON-POWDER PREFORMS.** Forging of powder preforms is a technique that closes the gap between normally produced powder metallurgy parts and high quality forgings. The present paper outlines the basic hot forging characteristics of iron powder preforms. Preforms made of hydrogen reduced iron powder were sintered and then hot-forged at various temperatures in the range of 800°C to 1100°C. The highest hardness and density were observed on specimens hot forged in the ferritic range. (Author abstract) 9 refs.

**084439 THEORETICAL ASPECTS OF COMPACTION OF DIELECTROMAGNETIC POWDER METALLURGY MATERIALS.** Dielectromagnetic and magnetodielectric are terms referring to materials consisting of a magnetic material (predominantly iron powder) and a dielectric. In dielectromagnetics magnetic features prevail over dielectric ones, whereas the opposite applies in magnetodielectrics. Particular features of the compaction of dielectromagnetic materials and factors affecting the attainment of required density are described and discussed. The dependence of density on compaction pressure is approximated by an exponential curve. Models are presented illustrating the effects of compaction on magnetodielectrics with various dielectric/pore volume ratios as well as changes in particle shape, cold work, and internal stresses. The possibility of improving magnetic properties of dielectromagnetics by recrystallisation annealing is considered. (Edited author abstract). 2 Refs.

**084440 HARDNESS AND WEAR OF HOT-PRESSED Fe-Cr-Mo-C-Si AMORPHOUS ALLOY POWDERS.** Powder of amorphous Fe-16Cr-8Mo-18C-4Si having a size below 25 µm has been produced by ultrasonic helium atomization. A fully dense material with finely and homogeneously mixed structure of B + M<sub>7</sub>C<sub>3</sub> + M<sub>6</sub>C phases can be obtained by hot pressing at 1300 to 1350 K. The packing fraction is about 100% and the particle size and the interparticle distance of the carbides are 0.6 - 1.0 µm and 1.2 - 1.9 µm, respectively. The alloy has high hardness, e.g., 965 DPN at room temperature and 400 DPN at 1 073 K as well as good wear resistance which is comparable to the highest value of commercial wear resistant high alloy steel. 19 refs.

## Iron Boron Molybdenum Alloys

**084441 EFFECTS OF Mo CONTENT AND SINTERING TEMPERATURE ON THE STRENGTH, HARDNESS AND DENSITY OF Fe-6 MASS% B-x MASS% Mo ALLOYS.** The ternary Fe-6 mass% B-x mass% Mo alloys have a composite microstructure consisting mainly of a complex boride Mo<sub>2</sub>FeB<sub>2</sub> as a hard phase and a ferritic binder. Both hardness and strength are improved by Mo addition due to formation of the high strength phase Mo<sub>2</sub>FeB<sub>2</sub>. The hardness increases monotonically with increasing Mo content. Alloy density also increases with Mo content. The highest strength was obtained for an Fe-6 mass% B-48 mass% Mo alloy in

which a small amount of brittle Fe<sub>2</sub>B formed as a result of a reaction in the compact. The composition Fe-6 mass% B-53 mass% Mo at which Fe<sub>2</sub>B is expected to be eliminated was found to lead to a reduced strength owing to a high sintering temperature required for complete densification. Decreasing of the Mo content below 48 mass% results in the excessive formation of Fe<sub>2</sub>B and leads to degraded strengths. (Edited author abstract) 17 refs.

Ide, T. (Toyo Kohan Co, Kudamatsu, Jpn); Nakano, K.; Ando, T. *Powder Metall Int* v 20 n 3 May 1988 p 21-24.

## Iron Chromium

**084442 INFLUENCE OF DISPERSION AND SUPERFICIAL APPLICATION OF RARE EARTH OXIDES ON THE HIGH TEMPERATURE OXIDATION OF Fe-20Cr SINTERED ALLOY.** The effects of dispersion and superficial application of rare earth oxides (Y<sub>2</sub>O<sub>3</sub>, La<sub>2</sub>O<sub>3</sub>, CeO<sub>2</sub>, Eu<sub>2</sub>O<sub>3</sub>, Gd<sub>2</sub>O<sub>3</sub>) on the isothermal oxidation of Fe-20Cr sintered alloy have been studied at 1373 K in air. The dispersion of these rare earth oxides reduced the oxidation rate but the effect was dependent on the kind of dispersoid. The dispersion of La<sub>2</sub>O<sub>3</sub>, Y<sub>2</sub>O<sub>3</sub> and Gd<sub>2</sub>O<sub>3</sub> reduced the oxidation rate, while the effect of Eu<sub>2</sub>O<sub>3</sub> dispersion was less than that of the other oxides. The dispersion of rare earth oxides except Gd<sub>2</sub>O<sub>3</sub> had a negligible effect on the oxidation rate. The results suggest that the rare earth oxides suppressed outward migration of Fe ions through the Cr<sub>2</sub>O<sub>3</sub> scale. (Edited author abstract) In Japanese. 7 refs.

Nagai, Hiroshi; Sawayama, Tetsuya; Shoji, Keiichi. *J Jpn Soc Powder Powder Metall* v 34 n 5 Jul 1987 p 222-228.

## Iron Chromium Aluminum Alloys

**084443 EXPLOSIVE COMPACTION OF Fe-25Cr-5Al HEAT RESISTING ALLOY POWDERS.** An optimum E/M ratio was determined to be between 3.5 and 4.0, where no cracks were formed in the compacts. The specific density ratio of the compact reached 98%. Although the tensile strength of as-compacted material was 12 kgf/mm<sup>2</sup>, strength was increased to 80 kgf/mm<sup>2</sup> by post sintering treatment. Oxidation behavior of the explosively compacted material was comparable to melted and forged material and superior to conventionally sintered and hot pressed materials. Hardness of the explosively compacted material in the temperature range from 400°C to 1,000°C represented a higher value than that of the melted and forged material. This result and the high tensile strength mentioned suggest that the powder boundaries were strengthened by dispersed oxides from the initial powder surface during explosive compaction. (Edited author abstract) 22 refs. In Japanese.

## Iron Copper

**084444 INFLUENCE OF THE MIXING METHOD ON THE MICROSTRUCTURE OF SINTERED IRON WITH 8 WT% Cu.** The efficiency of the cementation of copper on iron sponge as a mixing method to achieve a homogeneous distribution of both metals before compacting and sintering in powder metallurgy parts production is demonstrated by means of scanning electron microscopy of polished surfaces and fracture surfaces. Through this mixing process a complete contrast between iron and copper is produced, so that even during short sintering times solid solution formation is complete, thus achieving more uniform mechanical properties, compared with those attained by mechanical mixing. Cemented powders may be suitable for solid phase sintering (without copper melting), thus avoiding undesired dimensional changes. In English and German. 14 refs.

Pardo, A. (Univ Complutense, Madrid, Spain); Otero, E.; Merino, C.; Laguna, M. *Prakt Metallogr* v 24 n 7 Jul 1987 p 313-322.

**084445 CORROSION KINETICS STUDY OF SINTERED Fe/8% wt Cu BY MEANS OF ELECTRO-CHEMICAL METHODS.** The corrosion resistance of Fe/8wtCu sintered products in simulated atmospheres contaminated with SO<sub>2</sub> was studied. The importance of the mixing procedure during the preparation of the sintered products is stressed with special emphasis on the effectiveness of the cementation of the copper on the iron sponge in order to obtain products with a greater degree of corrosion resistance. In addition, the influence of sintering temperature, time and heat treatment on the kinetics of corrosion is analyzed thus establishing the optimum conditions of preparation. (Edited author abstract) 16 refs.

## Iron Graphite

**084446 OXIDATION OF CHROMIZED IRON-GRAPHITE MATERIALS.** We have investigated the oxidation process in air at 1140°K of iron-based porous materials subjected to diffusion chromizing. The specimens in the forms of cylinders were pressed from PZ4M3-iron powder with additions of GK-3 graphite (1.0, 1.5, and 2.0 wt.%) and zinc stearate (1 wt.%) with a pressure of 200 MPa. The metallographic investigations were made on a Neophot-2 microscope and the etchant was Grossbeck's reagent. The data of metallographic and quantitative micro-x-ray spectral analyses showed that diffusion chromizing leads to the formation of a diffusion layer. On the basis of the results obtained it is concluded that it is undesirable to use chromized porous iron-base materials as heat resistant ones at high temperatures in air. However, these materials may reveal high protective properties in weakly oxidizing gaseous media. An analysis of the kinetics of oxidation shows that materials with the minimum carbon content and the least porosity and given long diffusion impregnation are distinguished by the greatest heat resistance. 3 refs.

**084447 CATALYTIC EFFECT OF CARBONATES IN IRON-GRAPHITE COMPACTS.** Additions of certain alkali metal carbonates to iron-graphite compacts cause the generation of a carburizing gas atmosphere within the pores during sintering, and carbon alloying takes place efficiently and homogeneously at temperatures as low as 850°C if sintering is conducted in an inert gas furnace atmosphere. The process is believed to invoke the same catalytic cycle of reactions as that which is involved in pack carburizing. However, in the sintering case only those carbonates which react with carbon to produce alkali metal are effective, and then only if the vapour pressure of the alkali metal is high at the sintering temperature. Both sodium and potassium carbonate are efficient catalysts at 850-950°C. It is necessary to add more carbonate than will theoretically sustain the catalytic cycle within the pores. The excess is required to ensure that there is a net flow of reaction products from the pores, so that furnace gases cannot enter and dilute the carburising pore gases before all the graphite in the compact has reacted. ## Iron Nickel

**084448 PRODUCTION AND PROPERTIES OF POWDER ALLOYS FOR THERMOSTAT METALS.** This article presents technical features of production and the basic properties of powder metallurgy alloys with the minimum and high temperature coefficients of linear expansion for the passive and active constituents of thermocouple alloys. Powder metallurgy alloys with the minimum temperature coefficient of linear expansion were

produced based on Invar compositions including binary and those alloyed with cobalt (3.5%) and copper (up to 0.8%). For the constituent of the thermocouple alloy with the high temperature coefficient of linear expansion a low nickel alloy containing 27% Ni was alloyed with molybdenum in a quantity of 6.5%. The mechanism and kinetics of the synthesis process were studied on a  $(\text{Fe}_2\text{3-NiO-CoO-CuO}) + 4\% \text{NH}_4\text{Cl}$  system by thermogravimetric and differential thermal analyses. 4 refs.

## Iron Nickel Alloys

**084449 MECHANICAL PROPERTIES OF SINTERED Fe-Ni-P ALLOYS PREPARED WITH PLATED POWDER.** Mechanical properties of alloys sintered by using atomized iron powder which was electroless plated with nickel-phosphorus alloy were studied. The sintered alloys with plated powder showed higher tensile strength and larger elongation than sintered alloys with mixed powders. The microstructure of the sintered alloys showed a composite structure consisting of two regions. One is the intergranular region containing smaller iron particles where nickel content is higher. The other is the inside region of larger iron particles where iron remains low alloyed after sintering. This composite structure gives high tensile strength and large ductility of alloys sintered with plated powder. The relationship between the tensile strength and the content of nickel and phosphorus is represented by an equation. (Edited author abstract) In Japanese. 11 refs.

## Iron Silicon

**084450 MAGNETIC PROPERTIES AND STRUCTURE OF Fe-3 MASS%Si SINTERED ALLOY.** Magnetic hysteresis, induction at 800 AT/m ( $B_0$ ), maximum permeability ( $\mu_m$ ) and coercive force ( $H_c$ ) were measured using a recording fluxmeter and core loss ( $W_{50}$ ) was measured at 50 Hz and maximum induction of 0.5 T. The sintered alloy shows a hysteresis loop suitable for block magnetic cores at the sintering temperature range between 1473 and 1673 K. At this temperature range,  $B_0$  increases from 1.22 to 1.41 T and  $\mu_m$  increases from  $9 \times 10^{-3}$  H/m to  $1.5 \times 10^{-2}$  H/m linearly with density. On the other hand,  $H_c$  decreases from 84 AT/m to 48 AT/m linearly with density.  $W_{50}$  is improved at sintering temperatures higher than 1473 K and is almost constant (25.0 W/kg) at sintering temperatures up to 1673 K. Grain growth does not affect the coercive force since intermetallic inclusions are formed. (Edited author abstract) In Japanese. 5 refs.

## Iron Silicon Aluminum Alloys

**084451 HOT EXTRUSION PROCESS FOR FE-SI-AL ALLOY POWDER.** An alloy of 85 percent Fe-9.6 percent Si-5.4 percent Al exhibits high permeability and low hysteresis loss. Its use for magnetic applications has been limited because of poor workability. A new practice has been developed to form the alloy to full density from gas atomized powder. With this process, the alloy shows good workability at a high strain rate. The extruded material has good magnetic properties and improved mechanical properties compared with the conventional cast alloy.

Anon. *Trans Iron Steel Inst Jpn* v 28 n 5 1988 P416.

## Iron Tin Copper Alloys

**084452 INCREASE IN SINTERING ABILITY AT LOWER TEMPERATURE OF IRON-TIN-COPPER COMPACTS.** Studies are in progress concerning reduc-

tion of sintering costs for iron-base sintered products. It was found that the iron-tin-copper compact made from iron-base mixed powders with tin and copper additive powders showed better mechanical properties when sintered at about 900°C than the conventional iron-copper compacts sintered at about 1150°C. An attempt was also made to investigate the lower-temperature sintering of a new iron-tin-copper compact made from mixed iron-base powders, of which a little of an powder was admixed to iron-copper prealloyed powder. The resulting compact could be obtained when sintering at only 700°C and had superior mechanical properties. (Edited author abstract) 7 refs.

## Iron Titanium

**084453 HYDRIDING CHARACTERISTICS AND CYCLIC LIFE OF Fe-Ti-O ALLOYS.** The effects of powder size, environment and time on the hydriding process of  $\text{FeTi}_{1.15}\text{O}_{0.014}$ ,  $\text{FeTi}_{1.14}\text{O}_{0.023}$  and  $\text{FeTi}_{1.15}\text{O}_{0.024}$  were investigated by means of a volumetric method and differential scanning calorimetry. The change in the amount of hydrogen storage during hydriding-dehydriding cycles was also investigated by pressure-composition isotherms and X-ray analysis. It is concluded that a mechanism of hydrogen penetration through the phase boundaries plays an important role. The difficulty of  $\gamma$  hydride formation with increasing hydriding-dehydriding cycles can be explained in terms of hardening due to the high density of dislocations generated during the cycles. (Edited author abstract) 18 refs. In Japanese.

## Israel

**084454 ISRAEL.** The P/M-based industry in Israel is oriented mainly towards the production and development of high performance parts and materials. The sales of P/M oriented industries were about \$150 million in 1986 and these have been growing at about 10-20% a year during the last several years. More than 60% of the products produced by P/M methods are exported. More than 90% (in sales) of P/M products are full density high performance parts and components. The research activities in universities and other research institutions are primarily in the field of high performance P/M materials, rapid solidification, consolidation of powders to full density, design of high performance materials, investigation of microstructure, and properties of high performance materials produced by modern P/M methods.

## Italy

**084455 ITALY.** During the last ten years the growth of P/M has been considerable and generally faster than the evolution of mechanical mass production. From this standpoint, Italy does not differ from the main industrialized countries. Because statistical surveys and reports concerning market situations in Italy are not available, the trends and data presented are based on estimates made by people involved in the P/M industries. 5 refs.

Bocchini, Gian F. (Hoganas Italia srl, Como, Italy). *Int J Powder Metall (Princeton NJ)* v 24 n 2 Apr 1988 p 143-151.

**084456 VANZETTI - ITALY'S PIONEERING CARBIDE PRODUCER.** Metalloceramica Vanzetti of Milan is one of Italy's leading producers of cemented carbide indexable inserts and was the first to pioneer carbide production in that country in 1942. The present owners have decided to concentrate on carbide insert tooling. From the current production of 45 tonnes or 5 million pieces per year, around 80% comprises indexable inserts

for metal removal, the remainder being mainly wear parts and other types of cutting tools. This article is based on a plant visit.

**084459 JAPAN.** The export demand for Japanese industrial products decreased due to the rise of the Japanese yen in the foreign exchange market from September 1985. On the other hand, the domestic demand for these products has expanded because of the increase in personal consumption resulting from price stability and the lowering of interest rates. The total production of Japanese P/M products continued to increase in spite of the international oil crisis of 1975. These amounted to 153,671 tons in 1986, registering an increase of about 2% over the previous year. This is because production increases are being maintained in the automobile industry and the electric and electronic equipment industries, which are the main users of P/M products. 2 refs.

## Light Metals

**084462 ADVANCED LIGHTWEIGHT METALS USING RAPID SOLIDIFICATION.** The use of rapid solidification (RS) to improve the mechanical and physical properties of alloys based on the lightweight metals

aluminum, titanium, and magnesium are discussed. The alloying strategies used in the three alloy systems will be presented, and it will be shown how the attributes of RS have been utilized in designing alloys. The paper also demonstrates how RS has led to improved high strength/corrosion resistant, elevation temperature and low density aluminum alloys. In the titanium system emphasis to date has been on elevated temperature terminal and intermetallic alloys, and recent results will be presented. It will also be shown how RS of magnesium alloys has allowed circumvention of the low strength, low ductility and rapid corrosion rate typical of cast product. Consideration will be given to applications of these improved alloys, and some projections will be made on future developments. (Author abstract) 111 refs.

**084463 HIGH-ENERGY, HIGH-RATE MATERIALS PROCESSING.** The availability of pulsed power, high-energy kinetic energy storage devices offers an opportunity to perform a wide range of experiments. The power density/interaction time plot gives the regimes where the processing has the most potential. Processing approaches can be divided between direct and indirect techniques. HEHR processing is a potentially useful approach to powder consolidation for two reasons. The first is that the speed associated with the processing offers the opportunity to maintain the fine microstructure associated with the original powders in the consolidated material. This fine structure could be either a non-equilibrium microstructure or a fine grain or subgrain structure. The second is that the heating is concentrated at the interfaces of the conducting particles. 9 refs.

#### Molybdenum Iron Boron Alloys

**084464 EFFECTS OF CARBON CONTENT ON SINTERING MECHANISMS OF  $\text{Mo}_2\text{FeB}_2$  BASE HARD ALLOYS.** The liquid phase sintering of Fe-6wt. percent B-48wt. percent Mo-(0.01-0.55)wt. percent C alloys was studied by DTA, dilatometric measurements and microstructural observations. The liquid phase sintering accomplished by the formation of two liquid phases produced by  $\text{L}_1$  and  $\text{L}_2$  reactions, that is  $\gamma\text{-Fe} + \text{Fe}_3\text{B} \rightarrow \text{L}_1$  and  $\gamma\text{-Fe} + \text{Mo}_2\text{FeB}_2 \rightarrow \text{L}_2$ , when carbon content in the sintered alloy is low. As carbon content increases, another liquid phase reaction,  $\gamma\text{-Fe} + \text{Fe}_3\text{C} \rightarrow \text{L}_3$ , adds to  $\text{L}_1$  and  $\text{L}_2$ , which lies slightly below the temperature range in which the  $\text{L}_1$  reaction occurs. In proportion to the increase of carbon content, the temperature ranges of  $\text{L}_3$ , the  $\text{L}_1$  and  $\text{L}_2$  shift to lower temperature. When carbon content is in the range 0.01-0.55wt.%, the optimum sintering temperature lies slightly above the temperature at which the  $\text{L}_2$  reaction occurs. (Edited author abstract). 5 Refs. In Japanese.

**084465 PRODUCTION OF DEFORMED BLANKS FROM POWDERS OF COMPLEXLY ALLOYED CREEP-RESISTING ALLOYS.** In this investigation, centrifugal spraying of a rotating blank was used to produce powders of three creep-resisting alloys denoted PZhS, PDZh-1, and PDZh-2. The PDZh-1 and PDZh-2 alloys contained 4% W-8% Co-4% Mo and 8% W-10% Co-2% Mo. The chromium content of all the alloys was 10%, the hafnium content was 0.5-1%. The alloys were subjected to mechanical tests combined with structural

analysis to obtain information on the strength and ductility properties and the degree of preparation of the structure of subsequent deformation. The alloys show superplastic behavior in the temperature ranges examined but the rates at which this effect operates are low. 2 refs.

**084468 ON THE SINTERED Ni-BASE SUPERALLOY. (VII) - LIQUID PHASE SINTERING AND MICROSTRUCTURAL CHANGES OF MERL 76 POWDER.** DTA during the sintering and solidification processes of Merl 76 powder detected five endothermic and five exothermic reactions, respectively. Although the phase reactions during both processes occurred in approximately the same temperature range, microstructural observations and EPMA analyses revealed that the phase reactions during sintering were not the reverse of those during solidification. Rapid densification occurred in the temperature range of the first reaction, which corresponded to incipient melting. The microstructure consisted of a fine dendritic structure. The liquid phase appeared in the regions between the dendrite arms and the amount of the liquid phase increased, changing its composition with increasing holding time. (Edited author abstract) In Japanese. 12 refs.

**084470 SINTERING OF NICKEL-CONTAINING METALLIC OXIDE CERMETS.** It is possible to sinter nickel-containing cermets in a hydrogen-containing atmosphere when water vapor is present in that atmosphere and titanium oxide is present in the charge in an amount exceeding the equilibrium concentration of the  $\text{Ti}_2\text{O}_3$  solid solution in corundum. During calcining the titanium oxide is reduced, with the formation of a solid solution of  $\text{Ti}_2\text{O}_3$  in corundum and other phases, in particular  $\text{AlTi}_2\text{O}_5$ . This plays an important part in the densification of the material. Sintering can be improved by employing a fine

metallic nickel powder as the nickel-containing component. 6 refs.

**084473 PERFORMANCE OF NICKEL ALLOYS IN NITROGEN BASED ATMOSPHERES FOR SINTERING.** Nickel and iron base alloys were subject to nitrogen and hydrogen containing atmospheres over the temperature range 700°C (1292°F) to 1204°C (2200°F) to characterize the long term high temperature corrosion resistance of candidate alloys for P/M sintering furnace components, such as muffles and wire mesh belts. In addition, tests were also run in dry and wet ammonia atmospheres. Very low levels of oxygen in the atmosphere will retard nitridation by preferential oxide formation. Cyclic exposure with its concomitant air exposure is generally less severely nitriding than isothermal exposure. For the alloys of this study, the two most benign environments were nitrogen-cracked methanol and nitrogen-1% hydrogen both with added water vapor. In general, the higher the nickel content of the alloy, the more nitridation resistance of the alloy. Best overall performance was exhibited by Inconel alloy 600, which has the highest nickel and lowest chromium content among the alloys tested. 3 refs.

Rosa, Ed (Inco Alloys Int Inc, Huntington, WV, USA); Smith, Gaylord D. *Ind Heat* v 55 n 5 May 1988 p 15-17.

**084474 POTENTIAL OF POWDER INJECTION MOLDING AND HOT ISOSTATIC PRESSING OF NICKEL ALUMINIDE MATRIX COMPOSITES.** Intermetallic compounds are emerging as the next generation of high temperature, oxidation resistant materials applicable to turbines. Nickel aluminide is the initial choice as the matrix material. For injection molding a low density polyethylene wax with a softening temperature of 90°C was mixed with chopped alumina fiber and prealloyed nickel aluminide powder. The injection molding process and its difficulties are described. Proper mixing, slumping after debinding and presintering, reactive isostatic pressing and debinding of injection molded composites is discussed. It is concluded that debinding of coarse spherical powder is not possible without adequate support. The support is ideally in the form of a wicking material. With the wicking, the binder can be removed quickly (within 4 to 5 hours). The top surface slumps as soon as the binder liquifies, resulting in a depression on that surface. This is remedied by adding fibers, which increases the friction of the mixture. 7 refs.

### Nickel Chromium Cobalt Alloys

**084475 LOW COBALT POWDER METALLURGY SUPERALLOY.** With appropriate chemistry modifications, ZH56-K (Ni-11Cr-4.5Co-5W-5Al-3.5Mo-3Ti-0.15C-0.02B, weight %) has potential as a prospective low cobalt turbine disc material and was selected for investigation. The ZH56-K alloy composition was modified by increasing cobalt (from 4.5 to 5.5 wt%) and chromium (from 11 to 11.5 wt%) and adding 1.5 wt% niobium to increase strength. The powder was prepared by argon atomization and hot isostatically pressed at different temperatures to study the effects of consolidation temperature on microstructure and mechanical properties. The heat treatment, 1080°C/8h, rapid air cool + 650°C/24h, air cool + 760°C/16h, air cool, offered the best combination of tensile and stress rupture properties due to finely distributed carbide precipitates, coarse  $\gamma'$  precipitates at the grain boundaries and a bimodal distribution of intragranular  $\gamma'$  particles. Another heat treatment, 1220°C/2h, rapid air cool + 1050°C/8h, air cool + 850°C/16h, air cool, resulted in the formation of a continuous carbide network at grain boundaries and a high volume fraction of fine  $\gamma'$  particles with a raft-like morphology. This heat treatment resulted in reduced strength at high temperatures. (Edited author abstract) 19 refs.

### Nickel Chromium Iron Alloys

**084476 WARM SHOCK CONSOLIDATION OF IN 718 POWDER.** Explosive consolidation of the rapidly-solidified nickel-base superalloy powder IN 718 was accomplished. The effects of explosive type, explosive-to-powder mass ratio, powder container material and thickness, type of confinement, shielding material and preheating temperature were investigated. Conditions for satisfactory consolidation with good mechanical properties and low microcrack density were established. The best consolidation was achieved by using a double-tube design in which a flyer tube was explosively accelerated, impacting the powder container. The powder was pre-heated at 525°C and the initial consolidation pressure was calculated to be 18 GPa, resulting in approximately 20% apparent interparticle melting. The quality of the consolidates was evaluated by optical and electron microscopy and by tensile testing. (Author abstract) 27 refs.

### Nickel Chromium Molybdenum Alloys

**084477 PRODUCTION OF WATER AND GAS ATOMIZED POWDERS.** A metal powder can be produced in a large number of different ways. For alloys the choice is mainly between gas and water atomization and the manufacturer must find out how to produce the powder in the most economical way. Depending on alloy composition, required cleanliness with respect to various elements and inclusions, particle shape, sieve fraction and production volume, he can select the proper raw materials, melting procedures, atomizing process and handling methods. This article presents a comparison of costs for different powder process routes. The alloy chosen in this article is nickel with 30 weight-% chromium and 10 weight-% molybdenum.

L'Estrade, L.; Hallen, H. *Metallurgia* v 54 n 11 Nov 1987 p S6, S8.

### Nickel Iron Tungsten Alloys

**084478 DEFORMATION BEHAVIOR OF TUNGSTEN COMPOSITES.** Particle composites are a group of materials which include possibilities for developing new types of composites by powder metallurgy. Liquid phase sintered tungsten composites containing W/Ni/Fe and sometimes an addition of Co have spherical single crystals of tungsten (BCC) in a ductile matrix of around 52Ni/26Fe/22W (FCC). Compared to pure tungsten, the composite has good ductility (25-30% elongation to fracture). The deformation properties and its temperature dependence are the same as that for tungsten single crystals. The aim of this investigation was to find a relation between the total deformation of a particle composite and the local deformation of the particles and the matrix. The intention was also to investigate different test methods, especially the computerized image analysis method. 8 refs.

**Niobium** See Also NIOBIUM AND ALLOYS—Solidification.

**084479 PARTICLE MORPHOLOGY AND PROCESSING PROPERTIES OF NIOBIUM POWDERS.** The main methods of producing niobium powders are the sodium thermic and carbothermic techniques, atomization of molten metal with compressed gases, and hydrogenation-dehydrogenation. In order to perform various powder metallurgy operations in the manufacture of parts with predetermined properties, it is necessary to carry out experimental investigations of the particle shape, particle size distribution, mechanical characteristics (microhardness), and compressibility of the powder to be used. In this connection, a study was made of niobium powders produced by hydrogenation-dehydrogenation under laboratory conditions by the same method but with additional roll-burnishing, by atomization with compressed gas and by an experimental process. The sizes and shapes of particles and their surface topography were investigated. 7 refs.

**084480 PRODUCTION OF NbTi SUPERCONDUCTING MATERIALS BY USING NbTi POWDERS AND SUBSEQUENT ARC MELTING.** NbTi alloys for superconducting purposes are produced on an industrial scale by vacuum arc remelting or electron beam melting of ingots made of electron-beam melted semi-products of the pure metals niobium and titanium. Due to the high vapor pressure of titanium at the melting point of niobium, mainly titanium vaporizes, so that the concentration of titanium can vary considerably in the ingot. Furthermore, due to the wide solidification range in the Nb-Ti phase diagram, strong segregations can occur in the material. In order to achieve a high homogeneity, the ingots are often formed into rods, bundled and remelted. To simplify this relatively costly method of production, investigations were carried out as to which extent NbTi ingots with high homogeneity can be produced with powder metallurgical intermediary steps. This paper reports on the results obtained. (Edited author abstract) 4 refs.

**084481 PREPARATION OF DUCTILE Nb-Al POWDERS FOR THE FABRICATION OF Nb<sub>3</sub>Al SUPERCONDUCTORS.** The influence of rapid quench-

ing and hydrogenation on the structure and phase composition of niobium-rich Nb-Al alloys was investigated. Starting ingots were prepared by conventional arc melting of compacted powder mixtures. The phase diagram for Nb-Al, presented by Jorda et al., was confirmed in the examined concentration range up to about 30 at.% aluminium. Specimens were quenched with cooling rates not less than  $10^4$  K s<sup>-1</sup>, both from the solid and liquid state. A metastable extension of the niobium solid solution up to 27 at.% aluminium was obtained after quenching small droplets from temperatures  $T \geq 2200$  °C. Ductile Nb-Al powders of an average composition 'Nb<sub>3</sub>Al' were prepared with a combined hydriding-dehydriding process. (Edited author abstract) 28 refs.

### Nitration

**084482 NITRIDIERUNG VON AL-PULVERN NAHE AN DER SCHMELZTEMPERATUR DES METALLS.** [Nitridation of Al-Powders Near by the Melting Temperature of the Metal]. Apart from the carbothermal reaction method, the production of sinterable AlN-powder is based on direct nitridation of Al-powder in a stream of nitrogen. This report deals with an investigation of the nitriding reaction in the 525-660°C temperature range by way of differential thermal analysis (DTA). The findings are reproduced by treating small batches in a tube furnace. The products are characterized by X-ray diffraction and scanning electron microscopy and tested for sinterability. (Edited author abstract) 4 refs. In German and English.

**Processing** See Also METALS AND ALLOYS—Solidification.

**084486 BETTER PROCESSING WITH POWDER METALS.** Powder metallurgy technology - both in materials and processing methods - has developed significantly in the past few years. PM is becoming an increasingly attractive alternative to conventionally formed metal parts, and the developing area of metal injection molding promises to recapture some metal markets lost to plastics. Rapid solidification technology, high temperature sintering, hot-forging, hot-isostatic pressing, and new materials - such as nickel aluminides - also continue to develop. The article discusses developments in the field.

## Purification

**084487 PURIFICATION OF METAL POWDER.** For manufacturing high grade metal components like turbine disks, tools and other high stressed parts, it is significant to process only metal alloy powder with a very low impurity content. The high purity of these powders can be achieved by superclean processing during melting, disintegration and the subsequent handling of the material. Another way is the application of cleaning processes before compacting the metal powder. There are two main sources for detrimental impurities, namely, ceramic liner material which is to be used during melting, and adsorbed gases which will be picked up during powder production and handling. Many different methods have been developed in order to clean the metal powder immediately before the final compaction. Some of these methods are described in this paper. 3 refs.

## Quality Assurance

**084488 LIGHT AND SHADOW ALONG THE POWDER METALLURGICAL ROUTE.** This paper discusses the cost and the quality aspects of PM parts for structural applications. The cost considerations include a shorter processing path, the production of near-net-shape components, the most efficient use of raw materials and energy, the fabrication of complex shapes with close tolerances and assembling which is possible before sintering. The quality considerations are the homogeneous structures with (almost) no segregation, the fine microstructure, the controlled density and porosity, the good surface finish, the possibility of obtaining non-equilibrium structures, and the fabrication of metal-matrix composites. 6 refs.

## Reviews

**084489 INTELLIGENT PARTICULATE PROCESSING, NET SHAPE MANUFACTURING AND THE PRODUCTION OF NOVEL P/M MICROSTRUCTURES.** The melt prior to atomization is considered and the different refining, degassing and filtering methods are addressed. The detrimental role of inclusions, particularly in components to be utilized in low cycle fatigue applications, is discussed. The role of sensors, on-line feedback control, and the intelligent processing controls needed to ensure a given size powder distribution are considered. The processing methodologies which have emerged to produce composites and gradient microstructures, such as plasma processing, are reviewed. (Edited author abstract) 8 refs.

Apelian, Diran (Drexel Univ, Philadelphia, PA, USA). *Int J Powder Metall (Princeton NJ)* v 23 n 4 Oct 1987 p 249-259.

**084490 1988 P/M TECHNOLOGY REVIEW.** In the second annual P/M technology review, the author highlights advances and trends in 1987 and conjectures on what lies ahead. The review focuses on developments in materials and equipment, new products, and the metal injection molding process. It is based on a survey response among companies who are members of the Metal Powder Industries Federation. (Edited author abstract)

**Silicon Compounds** See Also CERAMIC MATERIALS—Silicon Nitride; SILICON CARBIDE—Microstructure; SILICON NITRIDE—Manufacture.

**084492 RECENT TRENDS IN COLD AND WARM ISOSTATIC PRESSING EQUIPMENT.** Cold isostatic pressing (CIP) technology has seen rapid diversification in Japan in recent years, with high pressure equipment now available to process new materials such as Si<sub>3</sub>N<sub>4</sub>, SiC, rapidly solidified metal powders, hardmetals, plastics etc. T. Nishimoto, Y. Kishi and T. Naoi of Kobe Steel Ltd. in Chuo-ku, Kobe, Japan, describe their company's recent developments in wet-bag and dry-bag CIP equipment, and also the introduction of a warm isostatic press. In the Japanese material producing industry, the intention to commercialize higher value-added materials has become very strong. Isostatic pressing technology is recognized as one of the most promising technologies to break through the technological barrier against the actual production of the above materials. There is demand for advanced CIP systems suitable for diversified specific purposes. In this paper, some of the newly developed CIP systems were described. Kobe Steel intends to contribute to the future progress of CIP technology through its advanced CIP system, which are based upon much experience with high pressure technology.

**084494 SINTERING WITH ADDITIVES.** The addition of Ni to the refractory metals W and Mo is used to describe the three stages of solid state sintering as well as postdensification by hot isostatic pressing. It is shown that densification phenomena are changed by the presence of additives via a simultaneous increase in grain boundary diffusivity and surface diffusivity. From experiments with W-Ni, Mo-Ni and Fe-Cu it is concluded that in the presence of liquid additives, the densification phenomena, rearrangement and center to center approach occur by particle disintegration, coarsening and directional grain growth. The influence of driving forces provided by a chemical reaction on the kinetics of mass transfer is discussed for diffusion-induced grain boundary migration and liquid film migration. These types of interface migration were caused by interdiffusion of the additives with the host metal. Liquid film migration is thought to be of importance for the homogenization of Fe-Cu and Fe-Cu-C alloys during liquid phase sintering. (Edited author abstract) 38 refs.

**084495 INTERACTION OF CHROMIUM CARBIDE (Cr<sub>3</sub>C<sub>2</sub>) WITH IRON MATRIX IN THE PRESENCE OF PHOSPHORUS DURING SINTERING.** In this work the effect of phosphorus on the dissolution process of the chromium carbide (Cr<sub>3</sub>C<sub>2</sub>) particles in an iron matrix was investigated with the aim of discovering the structure formation mechanism of the wear resistant alloy of the type CrCFe of chrome steels synthesized from a mixtures of the carbide with iron powders. It follows from the above that the reaction of the carbide Cr<sub>3</sub>C<sub>2</sub> with the iron matrix containing phosphorus has specific characteristics which distinguish it from the carbide diffusion mechanisms in pure iron or nickel which contains phosphorus. Actually, recrystallization of the Cr<sub>3</sub>C<sub>2</sub> carbide into the carbide M<sub>7</sub>C<sub>3</sub> appears as if it was retarded in the temperature range of 1100-1280°K in comparison with the development of this process in the Cr<sub>3</sub>C<sub>2</sub>-Fe system. Besides this, as a result of dissolving of the carbide particle in the iron matrix at a temperature of 1350-1380°K a crater

with a relatively smooth wall is formed in its place, whereas in the iron-phosphorus matrix a carbide eutectic crystallizes in that place. 6 refs.

**084500 NEUERE ANSCHAUUNGEN ZUM FESTPHASENSINTERING.** [Recent Views on Solid Phase Sintering]. Solid phase sintering of technical objects is fundamentally a high-temperature deformation process. In analogy to compact materials, this process can be understood as high-temperature creep. Depending on the powder particle size, the compaction in the stage of intensive shrinkage is caused either by diffusional creep, or by dislocation creep. (Edited author abstract) In German. 18 refs.

Schatt, Werner (Technische Univ Dresden, Dresden, East Ger). *Neue Huette* v 32 n 9 Sep 1987 p 325-329.

**084501 TRENDS AND DEVELOPMENTS IN MESH-BELT CONVEYOR SINTERING FURNACE DESIGN.** The mesh-belt conveyor furnace is the most

universally accepted furnace for sintering in the ferrous powder metal industry. The simplicity of the furnace design, outlined in this article, allows the furnace operator to maintain constant control over process conditions, thereby allowing constant product quality to be achieved. (Edited author abstract)

Smith, D.E. (Camlaw Ltd, Tamworth, Engl). *Metallurgia* v 54 n 11 Nov 1987 p S22.

**084502 VACUUM SINTERING FURNACES BOOST EFFICIENCY, RELIABILITY AND PRODUCTIVITY.** USA company Vacuum Industries Inc. has gained a world-wide reputation for the high performance characteristics of its vacuum sintering furnaces. This article outlines some of the current state-of-the-art models, together with some recent specific developments. (Edited author abstract)

Anon. *Metallurgia* v 54 n 11 Nov 1987 p S24.

**084503 OPTIMISED SINTERING IN NITROGEN-BASED ATMOSPHERES - THE NITRAZONE APPROACH.** Historically, the most common atmospheres used in the sintering of powder metal components have been endothermic gas, cracked ammonia and exothermic gas. Of these, endothermic gas found most general use, with exothermic gas and cracked ammonia being used for more specialized applications, e.g., sintering stainless steel in cracked ammonia. This article describes a system developed by BOC Ltd. (Edited author abstract)

Morris, J. (BOC Ltd, Shipley, Engl). *Metallurgia* v 54 n 11 Nov 1987 p S26, S28.

**084504 INVESTIGATION OF SINTERING OF WC-Co CEMENTED CARBIDE SYSTEMS IN A MAGNETIC FIELD.** The sintering of cemented carbide in a homogeneous and strong magnetic field is a new powder metallurgy technique. Experimental results demonstrate that the method efficiently improves the quality and structure of cemented carbides. A WC-(10-6)%Co alloy sintered in a magnetic field has a bending strength ( $\sigma_{bb}$ ) 20% higher, ratio of oriented WC crystals three items higher, and the  $\beta$ -Co (f. c.c.) content ten times higher than in alloys sintered without the use of the magnetic field. Its porosity is <0.02% (vol.). Substantial changes are observed both in its macro- and microstructure. (Edited author abstract) In Chinese. 8 refs.

**084505 ABNORMAL GRAIN GROWTH IN SINTERING POWDER COMPACTS.** The objectives of this paper are (i) to discuss the existing qualitative model for the initiation of discontinuous grain growth and (ii) to propose possible reasons for interpreting the development of faceted abnormal grains. The phenomenon of abnormal grain growth in sintering powder compacts in quite complicated. The presence of abnormal large grains or pore-boundary separation is not the primary reason for the initiation of discontinuous grain growth, but the correlation of the anisotropic grain growth, the purity level, the degree of agglomeration, and temperature should be considered. The faceting of grains is associated with the liquid phases. 17 refs.

**084507 PRODUCTION PLANTS FOR DEWAXING, VACUUM SINTERING, AND PRESSURE SINTERING IN A COMBINED PROCESS.** To eliminate porosity and thereby improve product quality of cemented carbides, hot isostatic pressing (HIP) with pressures = 1000 bar (Ar) was introduced in production in USA and Sweden during the year 1967. Moreover, besides a sintering furnace, also a separate high pressure HIP plant is also required. Just at the beginning of this decade, the realization took place that the 'defect healing of pores' can also be done in suitable equipment at lower pressures up to 100 bars isothermally in connection with the vacuum sintering procedure. With this method, equivalent good results were achieved at lower costs and at an improved grade of automation. 6 refs.

**084516 COLD FORGING OF SINTERED IRON POWDER PREFORMS.** Recently, sintered powder preform forging has been developed as a method for producing products of high density and with good mechanical properties. This paper reports on an investigation into the various aspects of cold forging of iron powder preforms which have been compacted and sintered from atomized iron powder. The influence of powder particle size, compacting pressure, sintering temperature and forging parameters on relative density of the preform was investigated. Considering the process of the forging of metal powder preforms under axisymmetric condition, the problems of pressure distribution at the die-work piece interface and the load have been analysed. The correctness of the yield criterion and interfacial friction law used during the analysis have also been verified experimentally.

Measurements were made on the development of barreling and strain variations at the free surface of the preform. The results so obtained are discussed critically to illustrate the interaction of various parameters involved and are presented graphically. (Author abstract) 24 refs.

**084517 RING-COMPRESSION TESTS ON SINTERED IRON PREFORMS.** Standard ring-compression tests have been carried out on sintered iron preforms of different initial densities. The values of the apparent strength coefficient and the strain hardening exponent have been estimated to identify which conditions of the preform result in mechanical properties closest to those of the equivalent wrought part. The coefficient of friction has also been estimated for compacts as well as for wrought parts, so that near identical frictional conditions could be employed for comparison purposes, in computations of their respective force requirements. Compacts of different length-to-diameter ratios have been prepared for different compacting pressures and the optimal conditions of the billet geometry for the least non-uniform densification along the length of the compact have been established. The main aim of this fundamental work was to prepare, and explore the properties of, sintered preforms of different initial densities and of a greater length-to-diameter ratio so that future cold Hooker studies on these compacts would be possible. (Edited author abstract) 4 refs.

**084518 DEFORMATION CHARACTERISTICS AND FRACTURING OF SINTERED COPPER POWDER STRIPS DURING COLD FORGING.** The industrial processing of sintered powder preforms has recently been developed for manufacturing various engineering components. The present investigation has been undertaken with a view to studying the deformation characteristics and fracture mechanism during the cold forging of sintered copper powder strips. The influence of compacting pressure, sintering temperature and forging parameters on the relative density of the copper powder strip is explored. Experiments have been conducted and measurements made on the development of barreling and strain variations at the free surface. Crack formation at the free surface has also been examined. The theoretical and experimental results are analysed and discussed critically to explain the deformation characteristics and the fracturing of sintered copper powder strips during cold forging. Results are presented graphically. (Author abstract) 22 refs.

**084520 PRODUCTION OF THIN TUBES AND TAPERED CUPS BY THE SPINNING OF SINTERED POWDER PREFORMS.** As an attempt to facilitate the small-batch production of axisymmetric parts such as thin tubes and tapered cups, a powder metallurgy technique has been employed in combination with a shear-spinning process. Electrolytic copper powder

is used as the starting material instead of a tube or a sheet and the powder is compacted within a simple device using a polyurethane cylinder as the pressure medium. The green compact is sintered in vacuum and then the sintered preform is spun to decrease its porosity and to improve its dimensional accuracy. The product obtained is annealed to diminish the brittleness arising from work-hardening in the multi-pass spinning. Finally, as an additional process to remove feed marks generated on the surface, the product is polished with sandpaper or a wiper roller. The relative density achieved by this process is about 0.98 and the dimensional accuracy, ductility and surface finish are also adequate for practical use. (Author abstract) 5 refs.

**084521 ANALYSIS OF SINTERING IN  $\alpha$  AND  $\gamma$  PHASES OF IRON BASED ALLOY USING WIRE MODEL.** A study of sintering in  $\alpha$  and  $\gamma$  phases of iron based mixed powder compacts has been made using specimens prepared by winding 200  $\mu\text{m}$  dia iron-molybdenum alloy wires around the same alloy spools. Changes in the size of the necks between wires were observed as a function of sintering time and temperature. By the 'exponential method', both the rate and the mechanism of sintering can be investigated. The neck growth rate was remarkably larger in  $\alpha$  phase than in  $\gamma$  phase, although the difference between the two phases was not clear in the mixed powder compacts. The sintering occurred mainly by lattice diffusion in both  $\alpha$  and  $\gamma$  phases, and additionally by surface diffusion in  $\gamma$  phase at lower temperature. (Author abstract) 13 refs.

**084523 DRUCKSINTERN VON  $\text{AlN}$  MIT  $\text{Y}$ -HALTIGEN ZUSATZSTOFFEN.** [Pressure Sintering of  $\text{AlN}$  with Y-Containing Additives]. It is well known that  $\text{Y}_2\text{O}_3$  can serve as an effective sintering agent for  $\text{AlN}$  ceramics (1). Its influence derives from the formation of a liquid phase at sintering temperature, i.e., roughly 1800°C. During cooling, Y-Al-garnet (YAG),  $\text{Y}_3\text{Al}_5\text{O}_{12}$ , crystallizes out of the liquid phase. This report deals with the phase and microstructural development of Y-containing  $\text{AlN}$  ceramics as functions of the type and quantity of the Y-containing additives, the atmosphere and the temperature/time program of the sintering process. In English and German. 5 refs.

**084524 ON PHENOMENA APPEARING DURING SINTERING PROCESS OF THE IRON-TIN MIXED POWDERS COMPACTS.** Phenomena appearing during sintering process of an iron-1.0 wt% tin mixed powders compact were investigated in comparison with those of the iron powder compact. When the iron-tin mixed powders compact is being heated, tin powder particles become liquid at the melting-point of tin, 505 K (232°C). The tin-liquid penetrates into capillaries between iron powder particles above about 673 K (400°C) and with the rising of temperature up to about 1173 K (900°C), the tin-liquid

forms various tin-iron intermetallic compounds. When the temperature is above about 1273 K (1000°C), however, all the intermetallic compounds become  $\alpha$  phase iron-tin solid-solution having higher self-diffusion coefficient than the  $\gamma$  phase. The above phenomena make the compact have a higher strength as well as more shrinkage in comparison with those of iron powder compact at the sintering temperature of about 1423 K (1150°C). **084525 ROLE OF SAMSONOV'S STABLE ELECTRON CONFIGURATION MODEL IN SINTERING OF REAL SYSTEMS.** Previous studies have analysed the density and volume change in porous green compacts of crystalline materials depending on pressure, temperature and sintering period and how these changes are influenced by the powder characters. G.V. Samsonov's fundamental unified model on the formation of stable electronic configurations in condensed matters is discussed in this work. In the review, an attempt has been made to apply the model in sintering of alloys, metal-ceramic composites and special ceramics. Specific examples from aluminium bronze, brass, ferrous alloys containing phosphorus, heavy alloys, Al-refractory carbide composites, WC based cemented carbides, refractory carbides and covalent bonded solids have been included. (Edited author abstract). 27 Refs.

**084526 ALLOY PHASE STABILITY IN LIQUID PHASE SINTERING.** The criteria for identification of successful liquid phase sintering systems are reviewed to establish common phase diagram characteristics. These phase diagram characteristics are related to the thermodynamic interaction between the components that constitute the sintering system. The desired phase stability relations for liquid phase sintering are represented by the interaction parameters. In turn, the phase stability is related to the electronic structure of the components. These concepts provide a basis for analyzing the sintering behavior of various transition metals. (Author abstract). 21 Refs.

**084528 ON THE PROPERTIES AND ECONOMICS OF SINTERED IRON POWDER METALLURGICAL EXTRUDES.** Cold Hooker extruded iron compacts have been evaluated for density, mechanical and metallurgical properties, in the as-extruded, annealed and re-sintered conditions and the results compared with those for an equivalent wrought composition. The extent of densification occurring due to cold deformation of the P/M compacts has also been examined. The commercial viability of the process of cold extruding a P/M preform has been analysed by considering the manufacture of a suitable component by the above process and comparing it with manufacture by the existing conventional process.

This evaluation gives an indication of the economics of the Hooker extrusion process of P/M preforms for the manufacture of a similar family of products. (Author abstract). 3 Refs.

**084529 PRESSURE ASSISTED SINTERING OF METAL ALLOYS AND CERAMICS.** The development of the pressure assisted sintering (PAS) process came about as a result of a two-year study of containerless hot isostatic press (HIP) treatment of pressed and sintered alloys. This work was started at the Gorham Advanced Materials Institute (GAMI) in 1977, and led to the patented PAS process. Shortly after the completion of this initial work, a study of the effects of HIPing on sintered rare earth cobalt magnets was undertaken. This article reviews the results of these early experimental programs, and shows how the results of these programs led logically to the invention of the PAS process for pressed, injection molded, gravity presintered and slip cast parts. The article also covers in detail the application of PAS to injection molded and die pressed P/M parts, the use of hot isostatic processing to densify intermetallic magnets, and the use of continuous sinter/HIPing of ceramics using pressures in the range of 200 to 30,000 psi.

**084532 COST MODELING RS POWDERS PRODUCED BY THE GAS ATOMIZATION.** Major factors affecting the cost of rapidly solidified powders produced by inert gas atomization have been identified by economic modeling. Case studies are presented for atomized aluminum and nickel-base alloy products. Input factors (e.g., materials, capital, labor, energy) and process costs (e.g., melting, atomization, collection, classification, handling, packaging) are compared for the two alloy systems. Raw materials constitute a major portion of the direct costs, and economy of scale can be achieved in both systems. The results are applied to aluminum and nickel powder. (Author abstract). 14 Refs.

**084535 SURFACE REACTIONS DURING ATOMIZATION AND CONSOLIDATION OF STAINLESS STEEL POWDER.** Mechanical properties of P/M-produced metals are influenced by the reaction products which form on the surface of the metal powder during the P/M process. To improve the understanding of the surface reactions, chemical characterization of the powder surfaces and interfaces of P/M ferritic and martensitic stainless steels has been carried out. During gas atomization of the steels, 10-15 nm thick particles of Mn- and Cr-oxides form on the powder surface at high temperatures. A 3 nm thick layer of Fe-oxide is formed at lower temperatures during cooling and handling of the powder. In the case of ferritic steel, 50 nm thick particles of Cr-carbonitride are also formed. Unlike gas atomization, atomization using the Rotating Electrode Process (REP) results in significant formation of Si-oxide on the powder surface. Si-oxide appears as a 2 nm thick layer and covers about 60% of the surface. The remainder of the surface is covered by Cr-oxide particles (6 nm) and a 3 nm thick Fe-oxide. The overall rate of oxidation at high temperatures is determined by the transfer of oxygen gas to the metal particle surface. The oxidation of the alloying elements is controlled by their availabilities and oxygen affinities. The reactions which take place on the prior particle boundaries (PPBs) during Hot Isostatic Pressing (HIPing) of martensitic stainless steel are strongly influenced by temperature. **084538 MOLD POWDER TECHNOLOGY FOR CONTINUOUS CASTING OF TITANIUM-STABILIZED STAINLESS STEEL.** Skin inclusions, a type of defect that detracts from the surface conditioning yield of continuously cast blooms of titanium-stabilized stainless steel, were presumed to result from high-melting point  $\text{CaTiO}_3$  that is formed when titanium in the molten steel is absorbed by the mold powder. The change in the properties of the mold powder after the absorption of titanium was investigated. When the basicity ( $\text{CaO}/\text{SiO}_2$ ) of the powder is above 1,  $\text{CaTiO}_3$  is formed and the powder increases in viscosity, but when the basicity is below 1,  $\text{CaTiO}_3$  is not formed and the powder decreases in viscosity. (Edited author abstract) 6 refs.

**084546 EFFECT OF COPPER AND BRONZE ADDITION ON THE SINTERED PROPERTIES OF 316L AUSTENITIC STAINLESS STEEL AND ITS COMPOSITES CONTAINING 4 VOL.%  $\text{Y}_2\text{O}_3$ .** Copper and bronze additions up to 3 mass% were made to 316L austenitic stainless steel and to mixtures of the steel and 4 vol.%  $\text{Y}_2\text{O}_3$ . Green compacts were subsequently sintered at 1300°C for one hour in dry hydrogen ( $-32^\circ\text{C}$ ). Linear shrinkage, radial shrinkage, densification parameter, sintered density and sintered porosity were measured. Corrosion resistance against  $\text{H}_2\text{SO}_4$  and mechanical properties were also evaluated. Improvements in the corrosion resistance were observed due to the addition of either copper or bronze. Bronze addition showed a comparatively better improvement. Optimum tensile strength and elongation were observed when 1 mass% copper or bronze were added to either straight SS or its 4 vol.%  $\text{Y}_2\text{O}_3$  containing composites. Hardness values are also higher for bronze additions. (Edited author abstract) 12 refs.

**084548 CORROSION BEHAVIOUR OF SINTERED AUSTENITIC STAINLESS STEEL FILTERS IN SULPHURIC ACID SOLUTIONS.** The corrosion behaviour of porous sintered 316L stainless steel in sulphuric acid media has been compared to that of a wrought material. Potentiodynamic polarisation studies and the variation of open circuit electrode potential with time have been used to evaluate the corrosion behaviour. The effect of porosity on corrosion has been examined. Compared to wrought material, the limiting current in the cathodic region is lower for sintered steels and the critical current in the anodic region is higher. The open circuit electrode potential of the sintered samples decreased continuously from 0 to -280 mV(SCE) after 40 h of exposure, then remained constant; for the wrought material, it increased from 0 to +150 mV(SCE), becoming steady after 25 h. SEM observations and XPS studies on the surface film revealed penetration of sulphuric acid into the specimen during corrosion. The overall trend in corrosion behaviour remained the same with changing electrolyte concentration. It is suggested that the inferior corrosion resistance of sintered samples is due to the formation of hydrogen ion concentration cells following entrapment of electrolyte in the pores. (Edited author abstract) 27 refs.

**084549 INFLUENCE OF SLAG PARTICLES ON THE MECHANICAL PROPERTIES AND CORROSION RESISTANCE OF A P/M AUSTENITIC STAINLESS STEEL.** A series of type 316 L stainless steels have been produced by hot extrusion of nitrogen atomized powders. High concentrations of non-metallic

inclusions have been introduced by atomizing a melt with a high sulfur content, by controlled powder surface oxidation or by mixing the powder with slag particles prior to extrusion. The slag levels influence both the impact strength and the tensile properties. The fatigue strength decreases with additions of large (500 µm) exogenous particles. The pitting corrosion resistance is also affected by additions of large exogenous slags and the corrosion resistance measured by the Huey test decreases when some of the slags are present. (Edited author abstract). 11 refs.

**084550 RECENT RESEARCH INTO THE USE OF TIN IN FERROUS AND NON-FERROUS POWDER METALLURGY.** This paper describes the sintering and aging properties of binary alloys in the composition range Cu/10-40%Sn and the ternary alloys Cu/1-20%Sn/1-20%Ni. The benefits of using prealloyed powder and temperature-programmed sintering regimes have been demonstrated. Aging of the ternary alloys by spinodal decomposition, which is a valuable property in the wrought materials, was observed in the powder metal samples. The use of tin in ferrous powder metallurgy has been more restricted but the advantages of making tin additions to stainless steel powders have now been clearly demonstrated. This paper summarizes the benefits to corrosion resistance of adding 1-2%Sn to AISI 304L stainless steel powder and indicates the probable mechanism. (Edited author abstract) 9 refs.

**084551 EFFECT OF METHOD OF MANUFACTURING OF HIGH-SPEED STEEL POWDERS ON THEIR COOLING RATE (REVIEW).** Investigations have shown that high rates of cooling of materials may lead, depending on their nature, to qualitative changes in the structural state of melts, such as substantial decrease in grain size, the formation of new metastable phases, and also the preservation of an amorphous state, which in turn can improve the properties of existing alloys and enable new materials to be created that cannot be produced by orthodox techniques. The effects are particularly pronounced when cooling is performed at ultrahigh rates. The results of a study of MI high-speed steel produced at cooling rates of  $10^6$  deg C/sec and higher are reported. On the basis of x-ray structural and electron microscopical examinations it is concluded that at ultrahigh cooling rates austenite formation is impeded, and a  $\delta$ -ferrite structure is preserved in the solidified state down to room temperature. Investigations of the carbide inclusions and structure in such materials have shown that a common property of high-speed steels produced at ultrahigh cooling rates is their greater solid-state homogeneity, due to inhibited formation and growth of second-phase particles during rapid solidification. 36 refs.

**084554 EFFECTS OF CARBON, COBALT, AND POWDER ANNEALING ON SINTERING CHARACTERISTICS OF BM2 TYPE HIGH SPEED STEEL.** Formation of grain boundary film and excessive grain growth restrict the upper useful sintering temperature for BM2 grade of high speed steel. Since cobalt bearing grades of steel, e.g. BM35, BM42, appear to have superior sintering characteristics, densification of cobalt enriched BM2 grades of HSS has been carried out - by vacuum sintering of cold compacted water atomized annealed powder. Cobalt additions of 2, 4, and 8%, however, did not lower the sintering temperature. A small decrease observed in the BM2 + 4% cobalt alloy, to 1245-1260°C from 1250-1260°C for the other compositions, was interpreted as a slight carbon enrichment of the particular powder batch, since the addition of elemental carbon was found to lower the sintering temperature. The effect of powder annealing conditions on the sintering behaviour was also studied. Vacuum annealing at 950°C was superior to hydrogen annealing at the same temperature which in turn showed better sintering response than hydrogen annealing at 900°C. In the sintered alloys the primary carbides were  $M_6C$  and  $MC$ . Additionally,  $M_3C$  type carbide was observed in BM2 + 8% Co and in the carbon enriched alloys. (Author abstract) 14 refs.

**084555 DYNAMIC PROPERTIES OF SINTERED STEEL.** Two sintered steels of identical composition (1.75 Ni-0.5 Mo-0.5C) were studied: one, with a coarse, pearlitic microstructure, produced from chemically homogeneous (water atomized) powder, and one, with a microstructure of ferrite, pearlite, and martensite, produced from chemically inhomogeneous (diffusion alloyed) powder. Four densities ranging from 6.6 Mg m<sup>-3</sup> to full density were included. The mechanical properties were investigated by tensile testing (monotonic and cyclic), impact testing, fatigue crack propagation, and fracture toughness testing. The results of the different testing modes are in qualitative agreement with the character of the corresponding fracture surfaces. It was found that the chemically homogeneous alloy has in general slightly better mechanical properties. (Author abstract) 26 refs.

**084556 BATTELLE PLAN COMMERCIALIZATION OF TWO-STAGE SPINNING CUP ATOMISATION PROCESS.** Battelle's Columbus Division in Columbus, Ohio, has developed a new two-stage rapid spinning cup (RSC) atomisation process which is expected to fulfill market requirements for fine metal powders used in a variety of applications. The capabilities of the RSC process, as demonstrated in Battelle's laboratory unit, are described in this article. This article briefly describes the

basic spinning cup atomisation process and its latest two-stage version. Some experimental results demonstrating the ability to produce fine powders and to control particle shape, size and size distribution are presented. An example of the level of impurity pick up in fine powder associated with the process is provided and the status of plans to develop the process to pilot- and eventually commercial-scale capacity is discussed. 3 refs.

**084558 GAS ATOMISED POWDERS ARE RAW MATERIAL FOR EXTRUDED BARS AND TUBES.** Within the Swedish Avesta Group is a leading manufacturer of steel powders and components. Avesta Nyby specializes in the production of extruded and HIP bar and tube. The powder production unit consists of two 6t induction furnaces and a vertical tower with recirculation of the gas. The unit has a maximum production capacity of 10,000t/year of powder. Avesta Nyby powders have a spherical shape which gives excellent free flowing properties, which is important in all thermal spraying and surfacing techniques. A further use for gas atomized superfine stainless steel powders is for the injection molding process, where the product offers a higher density feedstock and less shrinkage than water atomized or blended powders. 1 ref.

**084559 POWDREX HIGH SPEED STEEL BILLET PROCESS.** A new process for the production of powder metallurgical quality high speed steel bar and billet has been developed. The quality aspects depend partly on the ability of the process to produce a sintered ingot which is less than fully dense but which is sufficiently strong to withstand the stresses of forging. Material has been produced in different compositions and forged by a variety of methods and an understanding has been gained of the optimum ingot quality and forging method. (Author abstract) 3 refs.

**084560 HEAT TREATMENT OF POWDER METALLURGY CONSTRUCTIONAL STEEL (REVIEW).** This review of powder metallurgy steels covers the period 1960 to date. Some general conclusions are drawn. While following the general rules, the transformations in heating and cooling of a sintered steel have their own specific features caused by the presence of porosity, structural inhomogeneity, and inhomogeneity of the solid solution. The porosity and increased microdefect content have an influence on the position of the critical points, the austenitization process, and the transformations of supercooled austenite. The inhomogeneity of the solid solution formed in sintering alloy cement steels also changes the position of the critical points therefore in selection of the heat treat cycles, it is necessary to determine the critical points in each individual case. 50 refs.

**084562 TECHNOLOGICAL EXPERTISE EXTENDED IN HIGH ALLOY STEEL POWDER METALLURGY.** The production of high-speed steel by a powder metallurgical route developed by Powdrex Ltd. is shown to result in reduced manufacturing costs, uniform grain characteristics, excellent performance, and an ability to cope exactly with the most complicated shapes. Powdrex sintering technology has been applied, for example, to the production of rocker arm tips, push rod tips and cam rings, oil pump rotor vanes.

Anon. *Metallurgia* v 54 n 11 Nov 1987 p S10.

**084563 INFLUENCE OF SURFACE ROLL STRENGTHENING ON FATIGUE STRENGTH OF P/M SINTERED STEEL.** The process is an efficient way to improve the fatigue strength by surface strengthening. The paper describes the results of fatigue experiments on N-110 high strength sintered steel strengthened by surface roll strengthening. The fatigue strength was improved. (Edited author abstract) In Chinese. 4 refs.

Wu Rongwei (Beijing Research Inst of Powder Metallurgy, China); Liu Jianxin. *Fenmo Yejin Jishu* v 5 n 4 Nov 1987 p 207-209.

**084564 COMPARISON BETWEEN HOT ISOSTATIC PRESSING AND ROTARY FORGING FOR TOOL STEEL PRODUCTION.** Several properties of PM cold work tool steel D7 have been determined as a function of different hot consolidation methods. Gas atomized powder was processed by HIP and/or forging and investigated. Toughness, tensile strength, density and microstructure were examined. For certain dimensions there was no influence due to the method of consolidation. A hot forming operation after HIP or rotary forging further improved the mechanical properties of the PM material.

Stamberger, J.; Hribernik, B.; Jaeger, H. *Steel Times* v 215 n 11 Nov 1987 p 575.

**084565 HEAT TREATMENT OF HOT-WORKED P/M MEDIUM-MANGANESE STEELS.** The properties of P/M constructional materials produced under optimum processing conditions can in general be improved by reducing their porosity and at the same time ensuring that the distribution, shape, and size of the remaining pores are the least harmful. Suitable alloying and heat treatment is also necessary. In this connection, work was undertaken with the aim of improving the properties of hot-worked P/M medium-manganese steels by quenching directly after high temperature thermomechanical processing and by additional heat treatment. The hot working was performed by hot compression in a closed die and by hot extrusion. 4 refs.

Ananyan, K.E. (Novocherkassk Polytechnic Inst, USSR); Dorofeev, V.Yu.; Chumakov, V.I. *Sov Powder Metall Met Ceram* v 26 n 5 May 1987 p 372-375.

**084566 EFFECT OF POROSITY ON THE RELIABILITY OF MAGNETIC QUALITY CONTROL OF THE HEAT TREATMENT OF SINTERED STEELS.** Measurements were carried out on specimens of sintered steel 30NM. Variations in porosity cause large changes of hardness and imperceptible changes of the coercive force after hardening and tempering. That impairs the reliability of magnetic hardness control of heat treated products. To improve the quality of finished products, it is advisable to

use articles with known porosity for heat treatment. The porosity of products after sintering can be determined from the measurement of saturation magnetization and coercive force. 5 refs.

Ul'yanov, A.I. (Acad of Sciences of the USSR, USSR); Korobeinikova, V.S.; Sterkhov, G.V.; Sidorov, N.A. *Sov Powder Metall Met Ceram* v 26 n 7 Jul 1987 p 553-556.

**084567 SPECIAL FEATURES OF FAILURE OF R6M5 AND 10R6M5-MP HIGH-SPEED TOOL STEELS IN SUPERPLASTIC DEFORMATION.** The aim of this work was to examine the special features of failure of multiphase materials both in the SPD conditions and at different temperature-rate conditions of deformation. The investigations were conducted on R6M5 tungsten-molybdenum high speed tool steel with carbide hardening. For comparison, 10R6M5-MP high speed tool steel was examined. Deformation of both steels in the optimum temperature-rate conditions makes it possible to achieve high strains without the risk of failure even in the presence of an unfavorable (hard) stress state with mainly tensile stresses which open the pores. 13 refs.

**084568 EFFECT OF CARBON ADDITIONS ON SINTERING CHARACTERISTICS AND MICROSTRUCTURE OF BT42 HIGH SPEED STEEL.** The isochronal vacuum sintering behavior of BT42 after cold compaction of annealed water atomized powder is reported. Densities on the order of 99% theoretical were achieved. For the as-received powder the sintering temperature range was 1245-1260°C. The effect of adding nominal 0.01% elemental carbon was negligible. For 0.1% carbon densification commenced at a lower temperature and the sintering range was reduced to 1230-1250°C. The addition of carbon had no deleterious effect on the microstructure. The primary carbides present in the microstructure (compositions, excluding carbon, in weight percent) were 9% $M_6C$  (4Co-4Cr-28Fe-14Mo-3V-47W), 13% $MC$  (1Co-4Cr-4Fe-15Mo-41V-35W), and  $M_3C$  (cementite). When the specimens were oversintered by 20 K, grain boundary eutectic carbides (4Co-14Cr-40Fe-20Mo-6V-16W) were also detected. (Edited author abstract) 35 refs.

**084569 CYCLIC DEFORMATION BEHAVIOUR AND LOW CYCLE FATIGUE OF SINTERED STEEL.** Two P/M steels with the compositions 1.75Ni, 0.5Mo, 0.5C and 0.8P, 0.3C have been investigated. The Ni-Mo steels were produced in two different ways: by a diffusion-alloying technique leading to a chemically and microstructurally inhomogeneous material and by atomizing producing a homogeneous state. The P-steel was produced from a powder mixture. The cyclic deformation behavior as well as the low cycle fatigue properties were determined from uniaxial cyclic testing in strain-control. The Ni-Mo steels cyclically soften at low strains and harden at higher strains, while the P-steel hardens at all but the smallest plastic strains. A decreasing porosity generally improves the low cycle fatigue properties. The microstructural influence on these properties decreases at increasing porosity. At higher strain amplitudes the inhomogeneous Ni-Mo steel exhibits the largest and the P-steel the lowest fatigue life. Toward the endurance limit the materials behave in the reverse order. (Edited author abstract) 13 refs.

Bertilsson, I. (Volvo Flygmotor AB, Trollhattan, Swed); Karlsson, B. *Powder Metall Int* v 20 n 1 Feb 1988 p 13-18.

**084570 FATIGUE PROPERTIES OF P/M HIGH SPEED STEELS.** On cylindrical samples of hot forged, heat treated, quenched and tempered P/M ASP 30 and cast M2 high speed steels fatigue testing experiments were performed. Fatigue life was much lower in M2 than in ASP 30, due to finer and more homogeneous microstruc-

ture of ASP 30. Specimens with polished surfaces had a much longer fatigue life than samples with ground surfaces, indicating fracture to initiate at the surface of the specimen. (Author abstract) 5 refs.

**084571 SEPARATE DETERMINATION OF  $M_6C$  AND  $MC$  IN POWDER HIGH-SPEED STEELS.** To determine  $M_6C$  and  $MC$  in high speed steels separately, an etching quantitative phase analysis method without a standard sample has been developed. Coexistent phases  $M_{23}C_6$  and  $M_7C_3$  do not interfere with the determination. Fast phase identification of  $M_6C$ ,  $MC$  and  $M_{23}C_6$  in the high speed steels can also be carried out by this method. (Author abstract) In Chinese.

Ma, Xiang (Central Iron & Steel Research Inst, Beijing, China); Luo, Sujuan; Zhao, Han. *Chin Shu Hsueh Pao* v 23 n 6 Dec 1987 p B311-B317.

**084572 DETERMINATION OF THE STRUCTURAL MORPHOLOGY OF EUTECTIC COATINGS FROM TECHNOLOGICAL FACTORS.** Specimens of 45 steel with a powder mixture consisting of gray iron, ferromanganese, a fluxing agent, and an activator applied to their face surface were placed in a furnace previously heated at 1280°C which provided heating at a rate of 10°K/sec (heating time to 1280°C 2 min), and were then cooled at different rates (0.5-150°K/sec). The structure of the coatings obtained was investigated with microscope and the phase composition was determined by x-ray analysis. The formation of coatings with hypoeutectic and eutectic structures on carbon and alloy steels is possible with a change in composition and thickness of the powder mixture, the temperature-time conditions of the process, and the cooling rate of coatings with a hypereutectic structure only with a change in the concentration of the components of the mixture. 9 refs.

Golubets, V.M. (Acad of Sciences of the Ukrainian SSR, Lvov, USSR); Pashechko, M.I. *Met Sci Heat Treat* v 29 n 7-8 July-Aug 1987 p 541-546.

**084573 HIP, HIP, HOORAY - FOR A SWEDISH FIRST.** With the world's largest hot isostatic pressing (HIPping) facility at its disposal, ASEA Powdermet in Sweden is claiming to have pushed powder metallurgy into new fields - for the alloys that can be made and the types of components produced. As far as alloying is concerned, ASEA Powdermet claims that HIPping opens the way for new families of materials, based on combining powders or combining powder with a conventionally-manufactured alloy. By these means it is possible to produce a component having layers of materials with different properties - a composite/compound.

Astrop, Arthur. *Mach Prod Eng* v 146 n 3729 Jan 1988 p 21.

**084574 EFFECT OF METHOD OF PROCESSING ON THE PHYSICO-CHEMICAL AND TECHNOLOGICAL PROPERTIES OF POWDER FROM SkKh15 STEEL SWARF.** In the course of investigations into mechanical comminution as a means of producing powder from SkKh15 steel swarf the problem arose of defining the boundaries of the ranges of physicochemical characteristics of powder particles ensuring that such powder possesses the necessary processing properties for its use in industry. A study was made of morphological characteristics and the effect of hardness and particle size analysis of the powder. Analysis of histograms reveals that, although each fraction contained a certain amount of elongated particles, the bulk of the particles were characterized by form factors of 0.74-0.82. With such a particle shape, satisfactory compactibility and flowability can be achieved. Lowering the carbon content of the powder improved its compressibility. At a carbon content of less than 0.2%, a level of compressibility was reached comparable with that of iron powders produced by the reduction

and atomization methods. In industrial production, annealing should be performed under carburizing conditions. 3 refs.

Kislov, V.G. (Scientific-Research Inst of Tractor & Agricultural Machine Construction, USSR); Stepnov, S.A.; Arabi, B.G.; Esikman, V.L. *Sov Powder Metall Met Ceram* v 26 n 8 Aug 1987 p 608-611.

**084575 SPECIAL FEATURES OF THE PRODUCTION OF LOW-ALLOY POWDER STEEL FOR STRUCTURAL AND ANTIFRICTION PURPOSES.** The objective of the work was optimization of the technological parameters of producing rollers from powder charge  $ZhGrO$ , 8D2N1 by a single compacting-sintering with subsequent hardening and tempering such that the rollers have the required structural strength and wear resistance. Another was study of the structure formation and properties. The material was a mixture with weight content of 0.8% graphite, 2% copper, 1% nickel, the remainder iron. The weight content of zinc stearate in the charge was varied in the range 0-1.5%. The use of a minimal amount of plasticizer (not more than 0.5%) in the compacted charge and molds with additional drainage made it possible with a single compaction and sintering to obtain highly dense powder products -  $(7.2-7.3) \cdot 10^3$  kg/m<sup>3</sup> - with a compacting pressure of 1000 MPa. Sintering for 3.6 ksec is accompanied by decompaction in consequence of degassing. Extending the sintering time to 10.8 ksec reduces the porosity and improves the mechanical properties. 6 refs.

Dorofeev, Yu. G. (Novocherkassk Polytechnic Inst, USSR); Geidarov, V.A.; Mamedov, A.T. *Sov Powder Metall Met Ceram* v 26 n 9 Sep 1987 p 725-728.

**084576 SOME SPECIAL FEATURES OF THE TEMPERING OF POWDER STEELS.** The investigations were carried out on steels ZhGr1.3 and ZhGr1G1 which were annealed, compacted and sintered. The results show the dependences of hardness, tensile strength, and impact toughness on tempering temperature. More homogeneous steel has greater hardness both after hardening and after tempering in all regimes. The speed of martensite disintegration increases with increasing porosity. 6 refs.

**084577 SINTERING MECHANISMS IN VACUUM SINTERED M2 AND T15 HIGH SPEED STEEL POWDERS.** Significant differences are observed in the sintering response of high speed steel water-atomized powders between molybdenum (M) and tungsten (T) grades. This paper reports the results of a study of phase distributions in M2 and T15 grades during sintering with and without the presence of a liquid phase. Data from differential thermal analysis, optical and scanning electron microscopy (using EDS) are presented to illustrate the mechanisms operating for a variety of temperatures and times around the empirically-derived optimum conditions. The presence of a small volume fraction of liquid is necessary to achieve high densities. It is observed by hot stage scanning electron microscopy that small diameter powders are the first to melt because of their higher dissolved carbon content and high relative surface energy. 12 refs.

Bee, J.V. (Univ of Adelaide, Aust); Brewin, P.R.; Nurthen, P.D.; Wood, J.V. *Met Powder Rep* v 43 n 3 Mar 1988 p 177-180, 182-184.

**084578 POWDREX TECHNOLOGY FOR PM HIGH ALLOY STEELS.** This article describes the developments made by Powdrex Ltd of Tonbridge, England, in the field of high alloy steel powders. While Powdrex technology was originally developed for the production of tools for metal cutting, it is being extended to a range of hard wearing components. One of the recent developments is the introduction of tool steel powders which can be sintered in conventional mesh belt gas atmosphere furnaces and used to produce hard wearing components for demanding applications. Water atomised

high alloy steel powders have been used in two different consolidation processes: one for the production of near net shape components or 'preforms' and the second for the production of high speed steel sintered billets suitable for forging and rolling into bar or rod.

Brewin, P.R.; Nurthen, P.D.; Toloui, B. *Met Powder Rep* v 43 n 3 Mar 1988 p 186-187.

**084579 MANUFACTURE AND APPLICATIONS OF SINTERED HIGH-SPEED STEEL PREFORMS.** The production of near net shape PM high-speed steel components for wear parts and cutting tool applications is described. Powder particles which are mainly produced by atomization of a melt can be compared to micro ingots. Every segregation that occurs is limited to the size of the powder particles. When compared to conventional HSS, PM high-speed steels are more homogeneous products with improved mechanical properties. The paper also discusses the properties of some PM high speed steel material and provides examples of applications. 5 refs.

Wachling, R. (Sintermetallwerk Krebssoe GmbH, Radevormwald, West Ger); Arnhold, V. *Met Powder Rep* v 43 n 3 Mar 1988 p 188, 190-192.

**084580 NOVEL APPROACH TO PRODUCTION OF PM HIGH-SPEED STEELS WITH DISPERSION OF FINE ALUMINA.** There is a novel development underway at Kalumetals Inc. of Latrobe, Penna involving the production of PM high-speed steels containing a small percentage of dispersed aluminum oxide. Grinding swarf containing alumina particles can be reclaimed and used as a raw material for PM high-speed steels sintered to full theoretical density. The grinding swarf, which is available from finishing wrought high-speed steels, is mainly based on Mo and W-Mo grades such as M1, M2 or M7. Results are also given of bend test and hardness measurements on the alumina-dispersed steels. Bend rupture values for the 0.72, 0.82, and 0.87% carbon alloys are similar with average values in the 260-270 ksi (1800-1850 MPa) range. Hardness ranged from 63.5 Rc for the 0.72% C alloy to 65 Rc for the 0.87% carbon alloy. Results for triple tempered samples are also shown.

Anon. *Met Powder Rep* v 43 n 3 Mar 1988 p 193-194.

**084581 PROCESSING VARIABLES AND CUTTING PROPERTIES OF VACUUM SINTERED M2 AND T15 STEEL TOOLS.** Full density sintered T15 high-speed inserts tested in this research proved to be about three times more resistant to cutting tests than a conventional wrought material. The simultaneous control over carbon additions, sintering temperature and sintering time can produce, after sintering to about 96% of the theoretical density, fine and uniform carbide distributions which are maintained during HIPing to full density. A fine distribution of carbides as obtained by HIPing undersintered T15 to full density appears to be deleterious to the cutting properties of the material yielding higher values of flank wear than the full density sintered tool steel. 4 refs.

**084582 NOVEL ROUTE TO PM HIGH-SPEED STEELS/TOOL STEELS.** The Worl-Tech Metals Corp. of Carnegie, Penna., has commercialised a novel production route capable of producing powder metallurgy high speed steel billets weighing up to 2 tons which are then reduced by hot working and/or hot rolling down to the desired diameter before being cut into appropriate sections for use as tools. The company also has the capability to produce composite billets. Because of the rapid solidification process employed, the PM billets produced have an improved microstructure compared with conventional wrought high speed steel.

Anon. *Met Powder Rep* v 43 n 3 Mar 1988 p 199-200.

**084583 TiC-TOOL STEEL COMPOSITE WITH IMPROVED WEAR AT HIGH TEMPERATURES.** Research work by B.K. Lograsso and R.M. German at the Rensselaer Polytechnic Institute in Troy, New York, has

shown that the properties of ferro-tic materials can be improved at 650°C and higher. A composition based on a mix of elemental powders including 0.85 C, 8.6 Mo, 2 V, 5 Ni, 5 Cr, 0.1 B, 25 vol % TiC and balance iron produced a TiC-tool steel composite which gives good high temperature hardness, corrosion resistance and a compressive strength at 677°C of 848 MPa. The addition of 0.1% B aided the precipitation of carbides - VC, Cr<sub>23</sub>C<sub>6</sub>, Mo<sub>6</sub> C-type. Vanadium, which forms hard and stable carbides, accounts for the improved elevated temperature properties.

Lograsso, B.K. (Rensselaer Polytechnic Inst, Troy, NY, USA); German, R.M. *Met Powder Rep* v 43 n 3 Mar 1988 p 202.

**084584 TRANSFORMATION, DURING TEMPERING, OF ATOMISED POWDERS OF HIGH SPEED STEELS CONTAINING MOLYBDENUM, VANADIUM, AND COBALT.** The authors describe a study of the kinetics of retained decomposition and carbide formation during tempering of atomized Mo-V and Mo-V-Co steel powders in the range 100-750°C. The high speed steel powders were produced by nitrogen atomization of liquid metal. Alloying of 6%Mo steel powders with 8%Co alters the kinetics of austenite transformation and carbide formation during tempering. The various types of carbides precipitated are discussed and their effects on hardness are detailed. (Edited author abstract) 8 refs.

**084586 SURFACE ANALYSIS OF REP-ATOMIZED MARTENSITIC STEEL POWDER.** Martensitic stainless steel powders (Fe12Cr) were produced utilizing the rotating electrode process (REP). Four different alloys were produced. The sulphur and phosphorus contents were 0.01 mass% and 0.1 mass%. The surface composition of the powders was determined by ESCA (electron spectroscopy for chemical analysis) and AES (auger electron spectroscopy). Prior to the analysis the powders were handled in argon atmosphere. The cooling rate during atomization is  $5 \cdot 10^3$  K/s. SiO<sub>2</sub> and Cr<sub>2</sub>O<sub>3</sub> are formed as particles on the surface at high temperatures during atomization. At lower temperatures a thin continuous film of Fe<sub>2</sub>O<sub>4</sub> is formed. The average oxide thickness of the powders is in the range of 4 nm - 6 nm. With high sulphur content, Cr- and Mn-sulphides form on the surface of the powder. The coverage and the thickness of the sulphides are 8% and 50 nm, respectively. Even at the highest phosphorus level, no surface segregation of phosphorus or formation of phosphorus compounds were observed. (Author abstract) 16 refs.

Nyborg, L. (Chalmers Univ of Technology, Goteborg, Swed); Olefjord, I. *Powder Metall Int* v 20 n 2 Apr 1988 p 11-16.

**084587 SURFACE ANALYSIS OF PM MARTENSITIC STEEL BEFORE AND AFTER CONSOLIDATION: PART 1. SURFACE ANALYSIS OF POWDER.** Surface analysis of Fe12Cr martensitic steel powder was performed using electron spectroscopy for chemical analysis and Auger electron spectroscopy. The composition and thickness of the surface oxides are independent of powder particle size in spite of the difference in cooling rate between large and small metal particles. The liquid metal droplets solidify at or below 1400°C. Most of the oxide is formed during solidification. It is suggested that a mixed oxide (MnCr<sub>2</sub>O<sub>4</sub>) is produced. Above 1400°C no metallic oxide is formed due to the oxidation of carbon to carbon

monoxide. At very high temperatures manganese evaporates. During cooling the manganese gas is condensed and oxidised on the surface. (Edited author abstract) 12 refs.

Nyborg, L. (Chalmers Univ of Technology, Goteborg, Sweden); Olefjord, I. *Powder Metall* v 31 n 1 1988 p 33-39.

**084588 SURFACE ANALYSIS OF PM MARTENSITIC STEEL BEFORE AND AFTER CONSOLIDATION; PART 2. SURFACE ANALYSIS OF COMPACTED MATERIAL.** Martensitic steel powder (Fe12Cr) was consolidated using hot isostatic pressing (hipping) at three combinations of temperature, pressure, and time: 770°C/150 MPa/8 h; 1000°C/50 MPa/2 h; 1150°C/150 MPa/2 h. The two lower hipping temperatures were chosen to obtain fracture along the prior particle boundaries (PPBs). Thereby, it was possible to study the reaction products formed on the PPBs during consolidation using Auger electron spectroscopy. During consolidation at 770°C the manganese and chromium oxides formed on the surface of the powder during atomisation are coarsened. At 770 and 1000°C silicon, vanadium, and nitrogen diffuse to the PPBs and form compounds. After compaction at 1000°C no MnO was detected on the fracture surface, which indicates that MnO is reduced at higher temperatures. Raising the hipping temperature to 1150°C enhances densification, thus no PPB failure is observed. (Author abstract) 5 refs.

**084589 NIOBIUM-ALLOYED HIGH SPEED STEEL BY POWDER METALLURGY.** A philosophy for the use of strong carbide formers like niobium in high speed steels is described. It follows the concept of independently optimizing the compositions of the matrix (for maximum secondary hardening potential) and the volume fraction of the blocky carbides (for protection against abrasive wear). Atomization and powder metallurgical processing is described. In this way, a steel has been produced whose matrix composition is similar to that of AISI M2, and whose primary carbides are all of NbC type. Its composition is 1.3C, 2W, 3Mo, 1.6V, 3.2Nb (wt%). Because of its high stability, NbC is a much more effective obstacle to grain growth than the normal high speed steel carbides, and this allows substantially higher austenitization temperatures to be used. Despite its leaner composition, the Nb-alloyed steel matches the cutting performance of AISI M2, and its secondary hardening seems to be more persistent at high temperatures. (Edited author abstract) 39 refs.

**084590 DEVELOPMENT OF TOOL STEEL POWDERS FOR SINTERING PRESSED PARTS IN GAS ATMOSPHERES.** A range of powders directed towards smaller PM components in hard wearing applications of all types have been developed by Powdrex Ltd., Kent, England. The powders, based on molybdenum tool steels, bridge the gap between the diffusion alloyed nickel-molybdenum high carbon iron powders, and the 'super grade' powders normally sintered to full density and used for metal cutting. Depending on the grade, compositions are in the following ranges: Mo 1.5/5.0; W 1.5/6.0; V 1.0/3.0; Cr 2.0/4.0; C 0.6/0.9. These alloys contain high carbon to achieve high hardnesses, and compounds including carbides of vanadium, tungsten and molybdenum, which impart exceptional abrasion resistance.

Henry, Richard J. (Powdrex Ltd, Kent, Engl). *Ind Heat* v 55 n 5 May 1988 p 14.

**084591 CARBIDE DECOMPOSITION IN BT42 HIGH SPEED STEEL.** The carbides present in conventional and powder metallurgical BT42 steels are MC and M<sub>6</sub>C. Depending upon the cooling condition, M<sub>3</sub>C and M<sub>23</sub>C<sub>6</sub> may also occur. An intermediate cooling rate of 15°C min<sup>-1</sup> from the sintering temperature of 1250°C produces M<sub>3</sub>C, while prolonged heating at 700°C causes precipitation of M<sub>23</sub>C<sub>6</sub> and dissolution of M<sub>3</sub>C. This communication describes the carbides observed in powder

metallurgical BT42 oversintered by 40°C (resulting in total fusion) and the effect of subsequent heating on the decomposition of the carbide. 4 refs.

**084592 STRIP FABRICATION FROM POWDER METAL USING HIP/PEELING TECHNIQUES.** Fabricating an experimental 13% chromium, 2% aluminum alloy steel into strip first requires compacting gas atomized metal powder into a ring by hot isostatic pressing. Thin strip then is produced by peeling - a technique of machining a wide chip off of the outside diameter of the ring. This process and subsequent annealing are described with reference to surface finish and microstructures. Fabrication of strip by hot isostatic pressing gas atomized powder into large rings and peeling into strip can be a flexible and efficient method of producing strip up to 160mm. (6.2 in.) wide and 200 microns thick, provided: (1) the alloy is readily machinable; (2) microstructures are well controlled; and (3) the material is free of voids and non-metallic inclusions. The advantage of using gas atomized/hot isostatically pressed material is that it can produce thin strip that is free of macrosegregation and consistent in properties. 12 refs.

**084596 NEW HIGH STRENGTH PM STEEL FOR CLOSE TOLERANCE PARTS.** Because of the requirement for narrow dimensional tolerances, particularly close control of the chemical composition must be maintained. In the production of Distalloy AG Hoegaes employs two methods for bonding alloying elements to the iron particles: diffusion bonding and bonding with organic binders. Diffusion annealing minimises segregation by creating a bond between the iron powder and the alloying powder particles by hating the powder mix in a reducing atmosphere - resulting in partial prealloying therefore permitting the utilisation of much finer particles than those in plain mixes. An additional method of overcoming the problem with dusting and segregation is using mixes prepared using the Hoegaes STARMIX technology, a

technique of adding certain binders in combination with a mixing treatment which permits fine particles to be bonded to the iron powder particles.

Anon. *Met Powder Rep* v 43 n 6 Jun 1988 p 433.

**084597 P/M PISTON ROD ENDS MACHINING, FORGING COSTS.** Automotive piston rods, customarily forged and then machined, are prime candidates for conversion to near-net processes. Engineers at Sumitomo Metal Industries Ltd. are using a high-strength steel alloy powder to replace forged rods. The as-sintered automotive component avoids costs of forging and needs only secondary machining.

**084599 SINTERING PHENOMENA AND HEAT-TREATED PROPERTIES OF CARBIDES AND BORIDES PRECIPITATED P/M ALLOYS MADE OF H.S.S. POWDER.** Sintering of mixtures of high speed steel powder and boron containing ferrous alloy powders were studied to obtain carbide and boride precipitated wear resisting P/M alloys. The properties after heat treatment were examined. AISI M7 and carbon reduced M7 (0.5 percent C) powders were selected and Fe-B and Fe-Cr-B powders were used as additive powders. Fe-B powder was better than Fe-Cr-B powder as the boron-containing additive powder. In order to get good mechanical properties, boron content of the mixture was determined as (Mo at percent + W at percent)/B at percent = 1.0. (Edited author abstract). 27 Refs. In Japanese.

**084600 PROPERTIES OF HIGH COMPRESSIBILITY COMPOSITE-TYPE ALLOY STEEL POWDERS, 'KIP SIGMALOY'.** Composite-type alloy steel powders, KIP SIGMALOY, have been developed for the production of high density and heavy duty structural parts. The powders are characterized by metallurgically bonding fine particles of alloying elements on the surfaces of soft iron particles, and satisfy both compressibility at compaction and alloy diffusivity during sintering. SIGMALOY Cu powders, which contain 2 to 20 PERCENT Cu as an alloying element, suppress "copper growth" during sintering and hence improve sintered strength by 10 PERCENT and dimensional accuracy by 30 PERCENT, when compared with conventional powder mixes. SIGMALOY 215, 315 and 415 powders with compositions 2 to 4 PERCENT Ni-1.5 PERCENT Cu-0.3 to 0.5 PERCENT Mo attain compressibility equal to or higher than that of pure iron powders and improve the homogeneity of sintered specimens, resulting in over 10 PERCENT higher strength and toughness than those of sintered powder mixes. (Author abstract). 9 Refs.

**084602 NEW HIGH STRENGTH PM STEEL FOR CLOSE TOLERANCE PARTS.** The objective in developing designated Distaloy AG was to reach high strength and hardness in combination with high density and sufficient elongation by using a single pressing/single sintering route without any post-treatments. In order to produce a material with sufficiently high density, shrinkage of about 0.8% occurs during sintering; however, this shrinkage can be controlled in such a way that the dimensional precision is similar to that of more conventional PM steels. Distaloy AG is based on iron powder with additions of 8% Ni and 1% Mo.

Anon. *Met Powder Rep* v 43 n 6 Jun 1988 P433.

**084603 INFLUENCE OF SLAG PARTICLES ON THE MECHANICAL PROPERTIES OF A P/M HIGH SPEED STEEL.** A series of high speed steels based on the commercial composition ASP 23 has been produced by nitrogen atomization and hot isostatic pressing. Controlled amounts of slag particles have been introduced by atomizing melts with high concentrations of sulfur and nitrogen, by surface oxidizing the powder or by mixing the powder with exogenous slag particles prior to HIP. The influence of the slags on the microstructure, impact and bend fracture strength, fatigue properties and cutting performance has been investigated. The steel is sensitive to slag inclusions and mechanical properties and cutting performance are strongly influenced. The decrease in impact and bend fracture strength depends mainly on the inclusion size. Subsequent forging of the HIPed materials improves mechanical properties. (Edited author abstract). 11 Refs.

**084604 DEVELOPMENT OF AS-SINTERED P/M CONNECTING RODS FOR AUTOMOBILES.** The P/M forged connecting rod is in commercial use. However, this mode of manufacturing is at a disadvantage with respect to cost. As-sintered connecting rods for automobiles were developed via a combination of high strength powder and the optimization of rod shape. The latter was evaluated by the finite element method. A rectangular hollow beam was suitable for the powder material. Oil atomized 4100s low alloy steel powder was used because of its high strength and compressibility. It was mixed with graphite, compacted, sintered and machined. This processing sequence resulted in acceptable fatigue strength in the as-sintered condition. (Edited author abstract). 7 Refs.

**084606 SUPERPLASTIC BEHAVIOUR AND OPTIMUM WORK PROCESSING OF POWDER-CONSOLIDATED AND EXTRUDED NI-BASE SUPER-ALLOY.** Powder of nickel-base superalloy Mod. IN-100 was consolidated by hot isostatic pressing and recrystallized under the conditions of an extrusion ratio of 72% at 1,373 K and subsequent annealing at 1,343 K  $\times$  1 h. The superplastic behavior was investigated in the temperature range 1,223-1,423 K and range of strain rates from  $2.5 \times 10^{-4}$  to  $10^{-1} \text{ s}^{-1}$ . The conditions obtaining in the maximum strain rate sensitivity index,  $m$ , changed from the constant strain rate of  $10^{-2} \text{ s}^{-1}$  at temperatures above 1,303 K to the constant flow stress of 150 MPa below 1,303 K. It was desirable to decrease the temperature continuously for the purpose of keeping the maximum  $m$  during superplastic deformation in tensile test. (Edited author abstract) In Japanese. 10 refs.

**084607 EFFECT OF CONSOLIDATION TEMPERATURE AND BORON ADDITION ON MICROSTRUCTURE AND MECHANICAL PROPERTIES OF HOT ISOSTATICALLY PRESSED PM SUPER-ALLOY BASED ON Zr56-K.** The chemistry of a high performance cast superalloy, Zr56-K (Ni-10Cr-5Co-5W-5Al-3.5Mo-3Ti-0.2C-0.02B), was modified by slight reductions in carbon, titanium, and aluminium content and minor additions of niobium and hafnium. It was observed that, unlike carbon, an increase in boron content did not promote the formation of continuous precipitates at the prior powder particle boundaries. Increased boron content narrowed down the consolidation temperature range and changed the morphology of  $\gamma'$  particles from cuboidal to dendritic. Precipitation of an eutectic  $\gamma + \gamma'$  structure and formation of continuous boride films at the grain boundaries severely degraded the mechanical properties of the high boron PM superalloy that was consolidated at a temperature marginally above the  $\gamma'$  solvus. An optimum consolidation schedule was determined for the high boron alloy, which after a suitable heat treatment produced significant property improvement in stress rupture and tensile properties. (Edited author abstract) 19 refs.

**Titanium** See Also POWDER METAL PRODUCTS—Deformation; TITANIUM AND ALLOYS—Melting; TITANIUM CARBIDE—Manufacture; TITANIUM COMPOUNDS—Physical Chemistry.

**084612 EFFECT OF EUTECTOID  $\beta$  STABILIZING ELEMENTS ON THE DENSIFICATION AND TENSILE PROPERTIES OF TITANIUM POWDER COMPACTS.** The effect of Cr, Mn, Fe, Ni, Cu, and Si on sintering characteristics and tensile properties was investigated and compared with the case of Co addition. Fe and Ni had a good effect on densification. In the case of Si addition, a high sintered density ratio of 99% was obtained for the 2 wt% Si specimen. The other specimens of Ti-X (X=Cr, Mn, Cu) showed decreasing sintered density ratios with increasing amount of additional elements. Ti-2%Fe specimen showed the highest tensile strength. Though the elongation value of 8% obtained for the (a+ $\beta$ )-quenched Ti-2%Fe specimen was lower than the 14% of the (a+ $\beta$ )-quenched Ti-2%Co specimen, it could possibly be improved by heat treatment in the (a+ $\beta$ )-region. (Edited author abstract) In Japanese. 11 refs.

**084613 EFFECT OF TECHNOLOGICAL FACTORS ON THE PROPERTIES OF HIGH-DENSITY TITANIUM SPONGE COMPACTS.** It is important to choose judiciously the thermomechanical conditions of compact re-pressing, heating, and forging and to study their effect on the properties of sponge titanium. It has been established that the sponge processing method developed enables titanium to be obtained which is comparable in physicochemical properties and melting sponge titanium. The solid titanium obtained contained the following impurities: 0.04 Fe, 0.02 C, 0.01 Si, 0.025 N, 0.08 O<sub>2</sub>, and 0.006% H<sub>2</sub>. These figures meet the purity requirements for VT1-00 technical titanium produced by the generally adopted method. The new process has been

employed for making titanium blanks and forged valves and other components for industrial applications. 6 refs.

**084614 PREALLOYED TITANIUM POWDER METALLURGY - BARRIERS TO USE.** The technology of prealloyed titanium P/M has matured to the point where it is ready to be used as a bill of materials in high integrity applications, in particular the aerospace industry. Mechanical properties of powder parts are at least equivalent to those of the counterpart conventional ingot metallurgy products. In this commentary, the several generic technical and economic factors which determine the viability of a process and/or product are examined. These factors are considered in the specific case of prealloyed titanium P/M aerospace components. Actions that must occur if the cost-effective prealloyed approach is to be accepted are analyzed. (Edited author abstract) 9 refs.

Froes, F.H. (US Air Force Wright Aeronautical Lab, Wright-Patterson AFB, OH, USA). *Int J Powder Metall (Princeton NJ)* v 23 n 4 Oct 1987 p 267-269.

**084615 EVALUATION AND APPLICATION OF PREALLOYED TITANIUM P/M PARTS FOR AIRFRAME STRUCTURES.** Titanium powder metallurgy parts in the form of engine mount supports (EMS) were evaluated for use on the U.S. Navy's F/A-18A fighter aircraft. The parts were made to near-net shape by hot isostatic pressing (HIP) of pre-alloyed Ti-6Al-4V powder by the ceramic mold process. The powder was made by the plasma rotating electrode process (PREP), which produces powder that is free of contaminant particles. The evaluations included microstructural examination, hydrogen and oxygen analyses, dimensional inspection, radiographic inspection, residual stress measurement, and mechanical property testing. The latter included tests of tensile, compressive, shear, and bearing strengths; impact resistance, fracture toughness; stress corrosion cracking resistance; fatigue crack growth; and smooth S-N, notched S-N, strain-life, and spectrum fatigue behavior. The properties of the P/M EMS were equivalent to those of wrought material currently used to fabricate the EMS. (Author abstract) 2 refs.

**084616 TITANIUM POWDER METALLURGY-PRODUCTS AND APPLICATIONS.** The three facets of titanium PM, blended elemental, prealloyed, and rapid solidification, are reviewed in the following paper by F.H. Froes, D. Eylon and R.G. Rowe. The blended elemental approach has already been used for production runs of a number of components and introduction of a low cost chloride-free powder should greatly increase use. The prealloyed method exhibits mechanical properties at least equivalent to conventional ingot metallurgy product and appears to be very cost competitive especially for complex shapes which conventionally require extensive machining. However, acceptance is slow perhaps due to the conservation of the aerospace industry. It is suggested that the prealloyed approach will gain acceptance with the use of rapidly solidified alloys which can only be produced via PM, development of design data, lower cost powder, and introduction into new systems. (Author abstract) 65 refs.

**084617 BLENDED ELEMENTAL POWDER TITANIUM FOR AUTOMOTIVE APPLICATIONS.** A fully dense, blended elemental titanium powder metallurgy process (MR-9) was used to demonstrate a 70% weight savings over a conventional steel valve retainer cap. The same technology offers similar weight savings for connecting rods. This paper describes how retainer cap

was optimized for material properties and how parts were fabricated and tested. (Edited author abstract)

Brosius, E. (Clevite Industries Inc, Cleveland, OH, USA); Malek, J.C.; Petek, N.K.; Trzcinski, M.J. *Met Powder Rep* v 42 n 11 Nov 1987 p 768, 770, 773.

**084618 FUTURE OF TITANIUM POWDER METALLURGY.** Near-net-shape parts can be produced economically from elemental powders for numerous applications. In this paper the author discusses the current state-of-the-art of titanium powder metallurgy, then the current and potential markets for titanium powder metallurgy and near net-shape production; third, potential markets, and, last, some specific attributes of elemental powder. The author sees titanium powder metallurgy as being a viable partner to the wrought and cast titanium industry if the learning curves are followed intelligently in P/M parts manufacture and if pricing of titanium powders is such that the development of new and expanded markets can continue. 7 refs.

Fry, Robert K. (Micron Metals Inc.). *Light Met Age* v 45 n 3-4 Apr 1987 p 13-14, 16.

**084619 EFFECTS OF PURITY OF TITANIUM POWDER AND POROSITY ON STATIC TENSILE PROPERTIES OF SINTERED TITANIUM SPECIMENS.** Using two different kinds of titanium powders, some properties of P/M titanium specimens were investigated in relation to porosity. Hunter process sponge fines showed a better compressibility than Kroll process HDH titanium powders but the sintered density ratio of the former became nearly the same as that of the latter due to poorer shrinkage during sintering. Both tensile strength and elongation of the sintered HDH powder specimen increased nearly in proportion to the increased sintered density ratio. In the sintered Hunter process sponge fines specimen, there existed a flat region where the static tensile properties were nearly constant independently of sintered density ratio. In the fracture surface of the sintered Hunter process sponge fines specimen there were non-metallic inclusions identified as NaCl. (Edited author abstract) In Japanese. 10 refs.

**084620 EXPLOSIVE CONSOLIDATION OF TITANIUM POWDER WITH A PRESSURE MEDIUM.** This paper reports a new explosive consolidation procedure of metal powder that employs a pressure medium in order to induce the homogeneous transfer of shock waves. The trial manufacture of a complex form compact is also made by taking advantage of the proposed method. It can be deduced that the shock wave transfers isostatically to the innermost tube wall through the pressure medium in spite of the concentric configuration of the explosive. All experimental results presented here demonstrate the advantage of using a pressure medium for explosive consolidation of metal powders. 6 refs.

**084621 P/M TITANIUM TECHNOLOGY FOR HIGH PERFORMANCE USES.** A powder metallurgy process for titanium has been developed for high performance applications including aircraft engine and airframe components. The process utilizes high quality prealloyed powder produced by gas atomization or the PREP process. These powders have been consolidated into a variety of near-net shapes using the ceramic mold process and hot isostatic pressing. The resulting material is fully dense and exhibits mechanical properties which equal or exceed those of castings, forgings and plate. The process has been successfully applied to conventional and advanced titanium alloys, including the titanium aluminides. 13 refs.

Moll, J.H. (Crucible Materials Corp, Pittsburgh, PA, USA); Yoltan, C.F.; Chandhok, V.K. *Ind Heat* v 55 n 5 May 1988 p 24-27, 30.

**084622 DENSIFICATION OF TITANIUM POWDER DURING HOT ISOSTATIC PRESSING.** The densification of spherical and angular titanium powder during hot isostatic pressing (HIP) at 700°C has been studied. The angular powder densifies in a manner similar to the spherical powder despite its low initial packing density. Good agreement is found between a model for the HIP of monosize spheres and the experimental data for both spherical and angular powder provided that the transition between the initial stage of densification (contacts between individual particles) and the final stage (compact is a homogeneous solid with isolated pores) occurs at a density of roughly 95 pct of theoretical. This is consistent with observations of the pore microstructure as a function of density. (Author abstract). 20 Refs.

**Titanium Aluminum** See Also TITANIUM ALUMINUM BORON ALLOYS—Solidification.

**084623 POWDER METALLURGY OF TITANIUM ALUMINIDES.** Recent advances in prealloyed titanium aluminide powder metallurgy have now made it possible to produce fully-dense compacts with mechanical properties at least equivalent to those found in wrought material. Through powder metallurgy, it is possible to enhance functional properties by manufacturing bimetallic components that would be extremely complicated to make by conventional methods. The paper describes microstructure/property relationships in Ti<sub>3</sub>Al (alpha), TiAl (gamma), and bimetallic Ti<sub>3</sub>Al/Ti-6Al-4V hot isostatic pressed powders. Heat treat conditions, diffusion, and room temperature tensile properties were established. (Edited author abstract) 3 refs.

**Titanium Aluminum Vanadium**

**084624 CHARACTERISTIC PROPERTIES OF HOT ISOSTATICALLY PRESSED Ti-6Al-4V ALLOYS.** Static tensile properties of HIP Ti-6Al-4V alloys after sintering at 1473 K for 3.6 ks by blended elemental powder metallurgy process were studied and compared with those of HIP compacts made by the rotating electrode process (REP). The tensile strength and ductility after sintering using hydride-dehydride Kroll process sponge fines as the titanium source were nearly the same as those of the REP alloy. On the other hand, ductility degradation was observed in the case of using Hunter process sponge fines as the titanium source. This behavior is related to NaCl in the sintered compacts. (Edited author abstract) In Japanese. 7 refs.

**Titanium Aluminum Vanadium Alloys**

**084625 MANUFACTURE OF A NOVEL POROUS METAL.** A patented method of producing a novel type of porous metal is described, using as the matrix material the titanium alloy Ti-6Al-4V. Produced by consolidation of alloy powder in the presence of argon, the low density porous metal is generated by subsequent heat treatment. In the as-consolidated condition the material is close to theoretical density and can be hot worked to give primary sections such as plate, sheet or bar. During heat treatment kinetically controlled pore growth occurs to develop the required porosity level. Limited work has shown that porosity levels of close to 40% can be achieved. Although the work reported concerns Ti-6Al-4V, the technique is applicable to other titanium alloys as well as to other materials. (Edited author abstract)

## Titanium Carbide

**084626 EFFECT OF PARTICLE SIZE OF TITANIUM CARBIDE POWDER ON ITS HOT PRESSING UNDER HIGH PRESSURE.** A study was made of the hot pressing of titanium carbide powders of various particle sizes under pressures of 2.5-7.0 GPa at temperatures of up to 1800°C. Prior comminution has no significant activating effect on the sintering process, but leads to contamination by grain boundary impurities which adversely affects the strength of intergranular bonds. Specimens may fail as a result of nonuniform residual elastic strains during cooling under pressure and the fact that pressing in high pressure apparatus does not take place under hydrostatic conditions. The microhardness of titanium carbide grows with a rise in pressing temperature and pressure as a consequence of work hardening. 6 refs.

## Titanium Chromium

**084627 INFLUENCE OF CHROMIUM CONTENT ON THE TRIBOTECHNICAL PROPERTIES OF TITANIUM-CHROMIUM ALLOYS.** The purpose of this work was a study of the mechanical properties and wear resistance of titanium-chromium alloys containing 10-35%. Specimens prepared by pressing and subsequent sintering were investigated. Improvement in mechanical properties is accompanied by an increase in wear resistance. For alloys containing more than 20% Cr an increase in wear resistance is accompanied by a drop in mechanical properties. Such behavior is explained by the increase in content and structure of the TiCr<sub>2</sub> intermetallic formed. 8 refs.

Petrova, A.M. (Acad of Sciences of the Ukrainian SSR, USSR); Polotai, V.V. *Sov Powder Metall Met Ceram* v 26 n 5 May 1987 p 392-396.

## Titanium Cobalt Alloys

**084628 EFFECT OF TITANIUM POWDER ON THE CHARACTERISTIC PROPERTIES OF HOT ISOSTATICALLY PRESSED Ti-Co ALLOYS.** Static tensile properties of HIP Ti-Co binary alloys containing 2 wt% or 4 wt% Co were studied. Metallographic and fractographic observations were carried out by scanning electron microscope and X-ray energy dispersion analysis. Despite the low level of oxygen content, the specimen using Hunter process sponge fines as a titanium source showed poorer ductility properties than the specimen using hydride-dehydride Kroll process sponge fines of high oxygen content. The ductility degradation was related to the NaCl in the specimen using Hunter process sponge fines. Brittle fracture was due to the NaCl. (Edited author abstract) In Japanese. 9 refs.

## Titanium Compounds

**084629 HIGH-TEMPERATURE OXIDATION OF COMPOSITE MATERIALS BASED ON TITANIUM DIBORIDE.** Composite materials based on titanium diboride and a mechanical mixture of titanium diboride and carbide with Fe-Cr and Fe-Ni metallic binders are used for coating components working in conditions with abrasive wear and in corrosive media. This work examined high temperature oxidation of powders of composite materials with these binders (20% by mass) and corresponding dense specimens with a porosity of 2-3% in air at temperatures of up to 1770K by nonisothermal thermogravimetry and differential thermal analysis. The data on the stage mechanism of oxidation are in agreement with thermodynamic calculations in which the reactions taking place with the formation of boron and titanium oxide are the most preferred reactions. 4 refs.

## Titanium Iron

**084630 INTERACTION OF THE COMPONENTS IN Ti-Fe, Ti-Fe-Ni, AND Ti-Fe-Mn POWDER MIXTURES BY THE METHOD OF HOT MICROSCOPY.** Formation of the intermetallic TiFe in compacts of a mixture of titanium and iron powders occurs after sintering at 900-1000°C. Intermetallics are formed more actively under conditions of liquid phase sintering at temperatures exceeding the temperature of the first eutectic (1085°C). The existence of intermetallics in compacts being sintered before reaching of the eutectic temperature is an indication of solid phase interaction at the points of contact of the powder particles. The character of this interaction, which leads to the formation of eutectic concentrations containing 70 wt.% iron, was investigated. The microstructure during heating was studied in a vacuum with a pressure of  $12 \cdot 10^{-4}$  Pa. The phases were identified on the basis of high temperature x-ray diffraction analysis and chemical analysis. 5 refs.

**084639 ELECTRON-OPTICAL INVESTIGATION OF THE SINTERING KINETICS OF TUNGSTEN POWDERS OF SPHERICAL PARTICLE SHAPE. I. EXPERIMENTAL INVESTIGATIONS OF THE SINTERING OF TUNGSTEN POWDERS.** A study was made of the kinetics of contact formation and densification in the sintering of porous bodies from atomized spherical tungsten powders of mean particle sizes 4 and 10  $\mu\text{m}$ . Sintering was performed in hydrogen in the temperature range 1800-2000°C. Isoporous disks were produced by pressing with an addition of paraffin wax which was subsequently removed by slow heating to 800°C in hydrogen. To increase the strength of compacts used for pore size determinations by the Barus-Bechgold method, they were annealed for 0.5 h at 1400°C. A good correlation was found between pore sizes determined by the Barus-Bechgold method and those calculated with  $L=4/3 R_0/N-1(1-V/V_0^{2/3}-V)$ . 2 refs.

**084643 STUDY OF CARBURIZATION OF COARSE TUNGSTEN POWDER.** The carburization of W powder is a reaction diffusion process. The carburization proceeds from the outside to the inside of the polycrystalline W particles or the sintered agglomerates of W which function as reaction units. The coarser the W particles, the higher the temperature required for complete

carburization and the longer the time required. The authors studied the various conditions for carburization of coarse W powder and ways of eliminating  $W_2C$  in WC. (Edited author abstract)

Tao, Zhengji (Zhuzhou Cemented Carbide Industrial Co, Zhuzhou, China). *Int J Refract Hard Met* v 6 n 4 Dec 1987 p 221-225.

**084644 ELECTRICAL RESISTIVITY OF THE ACTIVATED SINTERED W-PRODUCT.** The electrical resistivity was measured for a Ni-activated sintered W-product compact after the pertinent elements had completed the alloying reactions. The relation between electrical resistivity and porosity of the sintered product was also examined with geometrical models to determine the electrical resistivity of the fully densified poreless product. The electrical resistivity of the 0.2% Ni-doped W-sintered product ranged from  $0.85 \times 10^{-5} \omega\text{-cm}$  to  $1.15 \times 10^{-5} \omega\text{-cm}$ , depending on the particle size of the W powder. This value is higher than that of pure W by a factor of two. (Edited author abstract) 12 refs.

**084645 RESULTS FROM THE MELTING OF TUNGSTEN COMPOSITES UNDER MICROGRAVITY IN SPACE (TEXUS 10 FLIGHT).** If a composite of low tungsten content is melted in space, the tungsten particles can grow freely floating in the molten matrix. The influence of surface energy, crystallographic anisotropy and attraction between the particles can be studied. After solidification the mechanical behaviour as a function of the amount of particles can be evaluated. The plastic deformation of the matrix compared to that of the particles is of principal interest. A primary test of the tungsten composite was undertaken in space using the Texus 10 module. During this test samples of two different compositions were melted. The results are given. 4 refs.

Ekbohm, Lars B. (Natl Defence Research Inst, Stockholm, Swed). *Int J Refract Hard Met* v 6 n 4 Dec 1987 p 231-232.

**084646 BOARD HORIZONS FOR P/M TECHNOLOGY.** (P/M) technology can form parts of tungsten and other difficult-to-melt metals at temperatures well below tungsten's 3000°F melting point. P/M parts can be designed so that after sintering (baking to weld the metal particles together), they arrive at net dimensions. In large runs (10,000 or more), P/M technology is often the least expensive way to produce parts. P/M also produces less waste and is more energy-efficient than many alternatives. Advances in impregnation have succeeded in preventing leakage, easing the use of plating and improving the machinability of P/M parts. Cadmium or zinc plating now may be applied to P/M parts. Machining P/M parts is notoriously difficult by filling the porosity with resin, machinability is vastly improved.

Rhodes, O. Thompson. *Des News (Boston)* v 43 n 12 Jun 22 1987 p 48-51.

**084647 EFFECT OF HEATING ON THE STRUCTURE OF ULTRAFINE TUNGSTEN POWDERS.** A study was made of the physicochemical properties and structure of ultrafine tungsten powders (UTPs) during heating to 1100°C. They were studied in the starting condition and after 30-min annealing in hydrogen at 300-1100°C. Determinations were made of changes in the specific surface of the powders and weight losses experienced during heating in hydrogen. The morphology and structure were investigated by transmission electron microscopy. 6 refs.

Skorokhod, V.V. (Acad of Sciences of the Ukrainian SSR, USSR); Panichkina, V.V.; Oleinik, G.S.; Novikov, V.I. *Sov Powder Metall Met Ceram* v 26 n 8 Aug 1987 p 611-614.

**084648 STRUCTURES OF SINTERED TUNGSTEN BARS AS EFFECT OF PRESSING LOAD.** The differences in structures of sintered W-AKS (doped

tungsten) which are dependent on pressing load at cold pressing the tungsten powder were analysed. High loads result in more closed pores and make the diffusion of doped elements to the surface difficult. Differences were found in the amount and distribution of pores as well as in the structure of the bars depending on the pressing load. (Author abstract) 8 refs.

Kolczynski, Z. (Warsaw Technical Univ, Warsaw, Pol); Rutkowski, W.; Swierczynska, M.B.; Trzaska, M. *Powder Metall Int* v 20 n 2 Apr 1988 p 22-26.

**084649 MECHANICAL PROPERTIES OF SINTERED TUNGSTEN BASE COMPOSITES.** This report describes the density, strength, toughness and ductility variations of tungsten base composites. Composites with additional nickel and iron (91.3 approximately 95.5%W/5.8 approximately 3.0% Ni/2.9 approximately 1.5% Fe) were fabricated by liquid phase sintering in a hydrogen atmosphere. In order to investigate deformation and fracture behavior, metallographic and fractographic examinations were performed in terms of a tension test,  $K_{Ic}$  test and Charpy impact test. The tensile strength, hardness and toughness are increased with increase in W content and swagging rate. The elongation is decreased with increasing W content and swagging rate. The mechanical properties are governed by the binding energy between the tungsten-matrix phases. The weaker this binding energy, the lower the ductility to failure. (Edited author abstract) 6 refs. In Japanese.

Kaneko, Takeshi. *J Jpn Soc Powder Powder Metall* v 35 n 2 Feb 1988 p 63-71.

**084650 STUDY OF POROUS COMPONENTS MADE OF TUNGSTEN POWDER PRODUCED BY THE SINGLE REDUCTION PROCESS OF HYDROGEN.** Sintering characteristics of tungsten powder with a mean particle size of 6.5 to 7.5  $\mu\text{m}$  singly reduced by hydrogen have been investigated. It is concluded that the relative density of porous tungsten components varies with the sintering temperature and time, particle size and green density. The parameters for producing porous tungsten products with relative density in a range of 78-81% and open porosity over 95% are outlined as follows: relative density of compacts, 60-65%; sintering temperature, 2100-2250°C; and sintering time, 4-8 hours. (Edited author abstract) In Chinese. 2 refs.

## Tungsten Copper

**084652 STEREOLOGICAL INVESTIGATION OF TUNGSTEN-COPPER PSEUDOALLOYS - II. EFFECT OF THE PRODUCTION METHOD AND OF THE PARTICLE-SIZE DISTRIBUTION OF THE INITIAL TUNGSTEN POWDER ON CHANGES OF THE MICROSTRUCTURE OF MATERIALS.** The communication submits the results of study of the size and shape of initial tungsten particles and of the effect of the method of producing them and of their particle size distribution on the evolution of the formation of the grain

structure in the process of producing the materials. The authors studied tungsten powders produced by the plants 'Pobedit' and the Uzbek Combine of High Melting and Heat Resistant Metals (UzKTZhM) in different modifications (PVN and PVT). 3 refs.

Paderno, V.N. (Acad of Sciences of the Ukrainian SSR, USSR); Pilyankevich, A.N.; Martynenko, A.N.; Pilipovskii, Yu.L.; Fal'kovich, L.D. *Sov Powder Metall Met Ceram* v 26 n 7 Jul 1987 p 543-546.

## Tungsten Nickel Iron Alloys

**084653 SINTERING TEMPERATURE EFFECTS ON A TUNGSTEN HEAVY ALLOY.** A 93 wt.% tungsten heavy alloy (W-Ni-Fe) was sintered from three different lots of commercial powder at five sintering temperatures. After sintering, two different heat treatments were employed. Variations in microstructures and tensile properties were measured to assess the effects of these three test parameters. The evaluation included density, hardness, tensile strength, elongation to failure, grain size, contiguity and volume fraction of matrix phase. The results show little significant lot-to-lot variation with respect to tensile properties. With higher sintering temperatures the elongation increases and the strength decreases. These changes result from microstructural coarsening at the higher sintering temperatures. The difference between the two post-sintering heat treatments is small and dependent on the sintering temperature. (Author abstract) 22 refs.

Bourguignon, Laura L. (Leach & Garner Co, Attleboro, MA, USA); German, Randall M. *Int J Powder Metall (Princeton NJ)* v 24 n 2 Apr 1988 p 115-118, 120-121.

**084654 INVESTIGATION OF THE PROPERTIES OF COMMERCIAL TUNGSTEN HEAVY METALS.** The development of tungsten heavy metals during the last decades has been intensive. One reason for this is the use of this type of alloy in armour piercing projectiles. To check the quality of commercial alloys an investigation of composition, microstructure, and different mechanical properties of such alloys was undertaken. The mechanical testing also involved different high strain rate tests. The investigation shows that the quality of commercial heavy metals has been improved during the last decade but that problems in production still exist. Among the alloys tested the best quality was found for a French alloy. 16 Refs.

## Tungsten Rhenium Alloys

**084656 MECHANICAL PROPERTIES AND STRUCTURE OF TUNGSTEN-RHENIUM POWDER METALLURGY DEFORMED ALLOYS.** In this work mechanical properties of tungsten alloys containing up to 2% rhenium were investigated. For this investigation the alloys were obtained by sintering of compacts of dispersed powders, which provided the formation of a tungsten-rhenium solid solution at relatively low sintering

temperatures. The blanks were deformed by rolling into sheet with a degree of deformation of 80%. For comparison three similarly treated alloys were investigated in parallel: (1) an alloy of tungsten with 2% rhenium; (2) an alloy of tungsten with dispersed additions of yttrium and hafnium oxides; and (3) commercially pure tungsten. The properties determined were the ductile-to-brittle transition temperature, bend strength, bend yield strength and crack resistance. 6 refs.

## United Kingdom

**084657 UNITED KINGDOM.** Since the last International Powder Metallurgy Conference in North America, the UK industry has seen a considerable change both in fortunes and in outlook. In 1984, at that time of the meeting, the worst of the recession was at an end, but at that time the industry was still attempting to see a way forward. Today, there is an atmosphere of optimism and a new drive is apparent. Within the UK, the industry has shed manpower, improved productivity and increased profitability. In this report each sector in turn is looked at and the results are reported. The intention is to concentrate on the main stream business and to comment on the present and future outlook. 2 refs.

## USSR

**084658 PLANT FOR THE PRODUCTION OF METAL POWDERS BY A CENTRIFUGAL HYDRAULIC METHOD.** At the Moscow Engineering and Physical Institute a pilot plant has been developed and undergone tests for the production of powders of nonferrous metals and alloys with melting points of up to 1273°K by centrifugal hydraulic atomization of melts. In the production of powder, metal is charged into a crucible and the column of the plant is sealed, evacuated to a working pressure, and filled with an inert gas to a pressure slightly exceeding atmospheric. Next, voltage is applied to the heating elements, and the metal is melted and heated to a temperature 2-5% higher than its melting point. 2 refs.

## Zinc Aluminum Alloys

**084662 FABRICATION OF A MAGNETIC COMPOSITE MATERIAL FROM Zn-22Al SUPERPLASTIC POWDER.** Air atomized Zn-22Al superplastic powder and ferromagnetic barium ferrite powder were mixed with various mixing ratios and compacted in a closed die at room temperature or 250°C. The compacts were magnetized in a strong magnetic field and converted into a permanent magnet. Magnetic characteristics of the composite material were almost equal to those of conventional plastic magnets. The magnetic composite material, as opposed to the conventional plastic magnets, provides essentially metallic functions such as good electric conductivity and re-formability. (Author abstract) 6 refs. In Japanese.

Okimoto, Kunio; Satoh, Tomio; Horishi, Nanao. *J Jpn Soc Powder Powder Metall* v 35 n 2 Feb 1988 p 47-52.

**084663 IMPROVEMENT OF SUPERPLASTICITY OF Zn-22Al PRE-ALLOY POWDER BY THE USE OF RAPID SOLIDIFICATION TECHNIQUE AND HEAT-TREATMENT METHOD.** Zn-22Al pre-alloy powders were fabricated by air-atomized, argon-atomized and rapidly solidified methods. The rapidly solidified powder was fabricated by centrifugal atomization. To improve the superplasticity of the air-atomized and argon-atomized powders, rapid cooling after heating at 380°C for half an hour was attempted. Microstructures of the rapidly solidified and heat-treated powders were observed by an optical microscope, SEM and TEM. Compactibility of the rapidly solidified powder was inferior to that made from the air-atomized and argon-atomized powders because the shape was nearly spherical. However, the refinement and homogenization of the rapidly solidified powder was similar to that of the heat-treated powders and elongation reached about 1000 percent. (Edited author abstract). 10 Refs. In Japanese.

## Zinc Compounds

**084664 PROMOTION OF ZnAl<sub>2</sub>O<sub>4</sub> FORMATION BY LiF: PART 1. EFFECT OF ALUMINA AND COMPACTION PRESSURE ON ZINC ALUMINATE FORMATION IN THE PRESENCE OF LITHIUM FLUORIDE.** The formation of ZnAl<sub>2</sub>O<sub>4</sub> in the presence of LiF was affected by the various states of Al<sub>2</sub>O<sub>3</sub> and by the compaction pressure. The rate curves showed a typical sigmoid form and were analysed by the Hancock and Sharp method. The results indicated a main process controlled by nucleation which is followed by a diffusion-controlled process. The effects of the aggregation or agglomeration state of Al<sub>2</sub>O<sub>3</sub> powder were examined with compaction pressures of up to 60 MPa. The amount of ZnAl<sub>2</sub>O<sub>4</sub> decreased with an increase in the degree of agglomeration or aggregation when the firing temperature was around 600°C but no effect was observed at higher temperatures. Similar effects were also observed for the compaction pressures. These effects are the result of the degree of formation of a liquid intermediate phase. (Edited Author abstract) 23 refs.

Hashiba, M. (Gifu Univ, Gifu, Jpn); Nurishi, Y.; Hibino, T. *J Mater Sci* v 23 n 2 Feb 1988 p 565-569.

**084665 PROMOTION OF  $ZnAl_2O_4$  FORMATION BY  $AlF_3$ .** Details of the formation of  $ZnAl_2O_4$  in the presence of  $AlF_3$  were studied for the purpose of elucidating the effect of fluoride anion on the reaction. In the  $ZnO-AlF_3$  binary system, sublimation of  $AlF_3$  and successive reaction of  $ZnO$  with  $AlF_3$  vapour were the first route of  $ZnAl_2O_4$  formation.  $ZnAl_2O_4$  formation with  $AlF_3$  was initiated at the  $ZnO-AlF_3$  interface as well as that of the  $ZnO-AlF_3$  binary system. This reaction was used to predict the formation of unstable zinc fluoride or zinc oxyfluoride. When the fluoride anions bound with zinc cations were transported to the surface of an  $Al_2O_3$  particle, the intermediate phase was formed at the site. In addition, the vapour transport of  $AlF_3$  to the  $ZnO-Al_2O_3$  interface was expected to form an intermediate phase containing fluoride anions such as  $Zn_xAl_yO_zF_y$  phase. The  $ZnAl_2O_4$  formation was promoted by the material transport through the intermediate phase around  $Al_2O_3$  particles. (Author abstract) 26 refs.

## Zirconium

**084667 EVALUATION OF PM PROCESSED ZIRCONIUM-2.5% NIOBIUM ALLOY.** Zirconium-2.5% niobium is an alloy commonly used in nuclear reactors and more recently chemical plants because of its corrosion resistance. As an alternative manufacturing method for producing certain irregular shapes more efficiently, the author has developed several different PM fabrication methods. Angular powder was prepared by the hydride-dehydride process. Spherical powder was manufactured by an electron beam atomization process. Microstructural and compositional variations were compared with conventional wrought processed material. Mechanical properties, corrosion behavior and weldability were also compared. 4 refs.

## Zirconium Compounds

**084668 NEUTRON DIFFRACTION ANALYSIS OF ULTRADISPERSE POWDERS OF ZIRCONIUM NITRIDE.** The article gives data on the specific surface of the powders as determined by thermal desorption of argon and data on the mean size of the particles of each nitride. The chemical formulae of the mixtures determined on the basis of the results of chemical and activation analyses and calculations are presented. These data show that the presence of the  $ZrO_2$  fraction confirms the value of the relative concentration of the nitrogen atoms in the nitride determined by chemical analysis. At the same time, the oxygen content of the dioxide is lower than its total content determined in activation analysis. On the basis of this result it may be assumed that parts of the oxygen atoms are distributed in the nitride. Several variants of the probable distribution of these atoms in the lattice were examined. 12 refs.

**084670 THEORETICAL PREDICTIONS OF OPTICAL BEAM ATTENUATIONS IN POWDER PIPE FLOW.** A theoretical model was constructed to model the interaction of single powder particle with an optical beam. From the transmitted waveform as a function of time, information about particle size, location and velocity can be obtained. Two theoretical models for the time-averaged transmitted fraction of an optical beam are the equivalent particle model and Monte Carlo simulations. Good agreement was obtained between the predicted results of the two models. With information on channel width, optical beam size and particle size, particle density can be obtained. 9 refs.

**084673 LOW FLOW RATE LABORATORY FEEDERS FOR AGGLOMERATIVE PARTICLES.** This communication has described the performance of a fluidization feeder and an entrainment feeder with  $Ca(OH)_2$ . The former has the advantage of higher solids concentration and lower carrier gas flow rates than the latter, but suffers the disadvantages of excessive noise from the vibrators and substantial particle agglomeration. In a system that can handle 2 to 3 l/min of carrier gas without an adverse impact upon the reactor environment, the entrainment feeder supplies a particle size distribution with little apparent sorbent agglomeration albeit at a lower, time-variant solids concentration. 3 refs.

**084675 EFFECT OF A STERICALLY STABILIZING SURFACTANT ON THE NUCLEATION, GROWTH AND AGGLOMERATION OF MONOSIZED CERAMIC POWDERS.** Hydroxypropyl cellulose (HPC) has been shown to provide steric stabilization during the precipitation of  $TiO_2$  from alcohol solution, allowing the precipitation of high solids loading of monosized particles by preventing agglomeration. The adsorption isotherm for HPC on  $TiO_2$  in ethanol was determined to account for the effect of HPC on the nucleation, growth and agglomeration of particles during the hydrolysis of titanium tetraethoxide in ethanol. Agglomeration is essentially prevented by HPC. (Author abstract) 21 refs.

Jean, J.H. (MIT, Cambridge, MA, USA); Ring, T.A. *Colloids Surf* v 29 n 3 Feb 15 1988 p 273-291.

**084676 STICKING AND AGGLOMERATION OF HYGROSCOPIC, AMORPHOUS CARBOHYDRATE AND FOOD POWDERS.** Sticking temperatures as a function of moisture content have been measured for various hygroscopic powders by use of a closed and agitated vessel held in a temperature bath. Earlier results reported by Downton, et al., for a mixture of sucrose and fructose have been extended to cover coffee extract and a mixture of maltodextrin, sucrose, and fructose. Results for these various substances are interpreted in terms of the Frenkel model and approximation, which postulate that these phenomena occur by a coalescence process, driven by surface energy and accomplished through viscous flow. The size of the interparticle bridge required for sticking is an important parameter in the analysis, and has been measured through use of scanning electron microscopy. (Author abstract) 23 refs.

Wallack, David A. (Univ of California, Berkeley, CA, USA); King, C. Judson. *Biotechnol Prog* v 4 n 1 Mar 1988 p 31-35.

**084677 SELECTION OF TEXTILE AUXILIARIES FOR REDUCING THE AGGLOMERATION OF CELLULOSE POWDER.** The authors describe the effect of TA (Textile Auxiliaries) which have been introduced in

the stage of hydrolysis of fiber waste on looseness of the powder. As a result of these studies, it was found that addition of the investigated TA during the hydrolysis of fiber waste reduces the bulk density of CP by 5-33% and essentially does not affect the sorption of water vapor by the powder. Oksamin L-15 and diethanolamine, introduced in the amount of 3% during the hydrolysis of the fiber waste, are effective additives. 2 refs.

## Amorphous

**084678 NEW APPROACH FOR THE DESCRIPTION OF THE INITIAL-STAGE KINETICS DURING AMORPHOUS MATERIALS SINTERING.** The sintering process, considered from a rheological point of view has proved to be a characteristic example of a relaxation process, development of which is conditioned by the tendency of a dispersion system to reach an equilibrium state. Consequently, macrorheology is of particular importance for the sintering process of amorphous materials, as this process results from local deformation and material flow. On the basis of the general principles of rheological theory and Frenkel's law for viscous flow, an equation is derived which describes the initial sintering stages of amorphous materials by a viscous flow mechanism. 6 refs.

Ristic, M.M. (Serbian Acad of Sciences & Arts, Belgrade, Yugoslavia); Dragojevic-Nesic, M.J. *Powder Technol v 49 n 2 Jan 1987 p 189-190.*

**084679 PRODUCTION AND CONSOLIDATION OF AMORPHOUS Ni<sub>63.7</sub>Zr<sub>36.3</sub> POWDER AND AMORPHOUS Cu<sub>60</sub>Zr<sub>40</sub> RIBBON.** Cu<sub>60</sub>Zr<sub>40</sub> amorphous powder of 210µm in diameter and Ni<sub>63.7</sub>Zr<sub>36.3</sub> amorphous powder less than 38µm in diameter as well as Ni<sub>36.5</sub>Zr<sub>63.5</sub> amorphous powder less than 10µm in diameter can be prepared by a special Ar gas-water atomization device. As long as the temperature of a warm pressed die is lower than the glass temperature of the amorphous powder or ribbon, an amorphous billet with a density of more than 99 percent can be obtained. The density of a Ni<sub>63.7</sub>Zr<sub>36.3</sub> amorphous billet increases with increasing temperature and pressure of the warm pressed die. (Edited author abstract). 7 Refs. In Chinese.

## Analysis

**084680 MICROANALYSIS OF SOLID SAMPLES BY TOTAL-REFLECTION X-RAY FLUORESCENCE SPECTROMETRY.** Microgram quantities of different solid powders and smears of alloys were analyzed with total-reflection X-ray fluorescence spectrometry, a special variant of energy-dispersive X-ray fluorescence spectrometry. The samples were analyzed directly without chemical pretreatment. The method works simultaneously for about 20 elements. Quantitative analysis with internal standardization was executed with 10-50 mg of sample mass, but only microgram quantities were necessary for the determination. Results for standard reference materials such as coal fly ash, bovine liver, tomato leaves, and electrical furnace dust are reported. (Edited author abstract) 17 refs.

**084681 ON THE DETERMINATION OF THE SURFACE FRACTAL DIMENSION OF POWDERS BY GRANULOMETRIC ANALYSIS.** We investigate the physical meaning of the exponent derived from the particle size (R) dependence of the surface area (S) of a solid powder, in cases where a power law S approximately R<sup>α</sup> is observed. In general, when the surface area is measured at constant apparent volume, α = D<sub>s</sub> - 3. D<sub>s</sub> is

the surface or textural fractal dimension of the particles, at least in the dimension range spanned by the particle size. On the other hand, when S is measured at constant mass, α = D<sub>s</sub> - D<sub>m</sub>, where D<sub>m</sub> is the mass fractal dimension of the particles, and the knowledge of D<sub>m</sub> is required in order to determine D<sub>s</sub>. D<sub>m</sub> is 3 either for compact or, on the opposite, for very porous particles in which the 'external' surface area is negligible with respect to the 'internal' surface area. In all the other cases, where the internal morphology of the particles is unknown, D<sub>m</sub> can be measured from the particle size dependence of the apparent density of the powder, ρ<sub>a</sub>, which scales as R<sup>D<sub>m</sub>-3</sup>. (Edited author abstract) 33 refs.

## Classification

**084682 ON THE MINIMUM BUBBLING VOIDAGE AND THE GELDART CLASSIFICATION FOR GAS-FLUIDISED BEDS.** Reported experimental findings for the effect of systematic variation of all the relevant variables on the bubbling point of gas-fluidized beds are shown to be in agreement with the predictions of a general fluid dynamic stability criterion for fluidization. The criterion is also applied to the evaluation of the stabilizing effect of fines addition and, somewhat speculatively, to the prediction of the boundary between the Geldart Group A and Group C powders. (Author abstract). 33 Refs.

Gibilaro, L.G. (Univ Coll London, London, Engl); Di Felice, R.; Foscolo, P.U. *Powder Technol v 56 n 1 Sep 1988 p 21-29.*

## Coagulation

**084683 EFFECT OF COAGULATION ON STEADY-STATE BROWNIAN DIFFUSION FOR PARTICLES WITH A FRACTAL STRUCTURE.** The treatment of Simons concerning the effect of particle coagulation on steady-state Brownian diffusion in a fluid, is extended to cover the case of particles with a fractal structure. It is shown that if a particular dimensionless parameter E lies within certain limits then the spatial variation of φ, the volume fraction of particulate material, exhibits a maximum, while if E exceeds the upper limit no steady state can be set up. It is suggested that measurements of φ could be used for the experimental determination of the fractal dimensionality of coagulating clusters. (Author abstract) 5 refs.

**084684 FEATURES OF THE THERMAL EXPANSION OF WATER IN PORES OF POWDERED AEROSIL.** Measurements of the thermal expansion of water in pores between particles of powdered Aerosil with a mean pore diameter of about 50 Angstrom have been described. A special version of Ur'ev's method for the vibratory compacting of powders was employed in order to eliminate the formation of aggregates of the particles. The results prove that the boundary layers of water at an oleophilic surface have a structure differing from the bulk structure. (Author abstract) 5 refs.

Deryagin, B.V. (Acad of Sciences of the USSR, Moscow, USSR); Karasev, V.V.; Chernomaz, V.E.; Ur'ev, N.B. *Colloid J USSR v 49 n 1 Jan-Feb 1987 p 11-13.*

**084685 COMPACTING POWDERED MIXTURES: A METHOD FOR INTENSIFYING CHEMICAL ENGINEERING PROCESSES.** The authors have devised and tested under laboratory conditions a method for compacting mixtures of fines of phosphorite, quartzite, and coke in a ratio providing for economically rational operating conditions for the electric furnaces used in phosphorous production. In this work, the manufacture of fiber glass and glass provide examples of the advantages of this compaction method. As a result of the analysis of the data obtained, three phases of consolidation were established: 1) consolidation due to elastic deformation of the framework of the powdered batch; 2) structural deformation of the components of the batch; and 3) destruction of the individual particles and the flow of components into the interior of the pressed material. It was established that there is a limiting pressure above which is observed the massive destruction of the particles of the batch, which leads to a rapid increase in energy expended for an insignificant increase in the density of the batch. 17 refs.

Chekhov, O.S. (Moscow Inst of Chemical Engineering, USSR); Kalygin, V.G.; Nazarov, V.I.; Shcherbin, N.V. *J Appl Chem USSR v 59 n 9 pt 1 Sep 1986 p 1838-1843.*

**084686 AUTOMATION TO THE FORE IN POWDER COMPACTING.** PTX-Pentronix of Lincoln Park, Mich., has introduced a new fully automatic hydraulic press system for powder compacting applications. The presses, which stem from Japan, are available from 20 to 1000 tons and can be custom modified to meet the user's specific needs. They are said to feature the latest advances in PC logic and also provide automatic part weight monitoring. This leads to decreased operator error with a consequent reduction of scrap to near zero and the manufacture of higher quality parts. Standard features of the system include: solid state controls; one-piece welded steel frame; withdrawal type die-set tooling; precision powder dispenser and safety devices (that meet or exceed OSHA standards). Optional features include: automatic robotic parts removal systems, quick die-set systems and an automatic weight monitoring and feedback system.

**084687 USE OF CUMULATIVE PORE VOLUME DIFFERENCE IN THE STUDY OF PORE CHANGES OCCURRING DURING COMPACTION OR SINTERING.** The feasibility of using differences in the cumulative pore volume distribution curves to monitor changes in the open pore size distribution as a result of the compaction of granules or the sintering of compacts has been studied. The cumulative pore volume difference distribution curve is obtained from the difference of two cumulative pore size distribution curves and illustrates clearly the pore volume difference at each pore size range. MnZn ferrite granules were used as an example. Increase and decrease of pore volume in larger and smaller pore size ranges respectively in sintering process and the opposite changes in compaction process were clearly recognized. The effect of the strength of granules in these processes was also studied. (Author abstract) 8 refs.

**084688 LE MAGNETOCOMPACTION DE POUDES: OBTENIR DES MATERIAUX INEDITS. [Electromagnetic Powder Compaction: Obtaining New Materials].** We present an experimental study on electromagnetic powder compaction. The classical method has been improved to give hybrid technique using both electromagnetic and impact phenomena. This technique is used to produce particulate composite materials. We have fabricated tubular aluminum-base compacts with dispersions of lead and indium up to 40% wt. Non-metallic phases like graphite, MoS<sub>2</sub> or PTFE have also been alloyed to metal matrices. In the same way we have made compacts including hard carbide particles in a cobalt or nickel matrix. These materials are interesting for their

tribological properties and we intend to use them for bearing applications. (Edited author abstract) 4 refs. In French.

Baccino, Regis (CEA, Fr); Parayre, Claude; David, Rene. *RGE Rev Gen Electr* n 9 Oct 1987 p 58-61.

**084689 AGGLOMERATE STRENGTH.** The bending strength of compacted powder samples was measured and compared with Rumpf's theory of agglomerate cohesion. It was discovered that the results could not be described by Rumpf's argument, which failed to account for the mechanism of failure, the pronounced effect of cracks, the problem of scatter in the strength determinations, the diameter dependence, and the volume fraction influence on strength. A new theory based on fracture mechanics analysis of an assembly of smooth adhesive elastic spheres gave a better fit to the data on titania and alumina powders. It is demonstrated that a perfect assemblage of particles should show a remarkably high strength. However, real assemblies are imperfect and weak because they contain small agglomerates which act as defects. Breakdown of these small agglomerates increases the strength of powder compacts substantially. (Author abstract) 23 refs.

## Contamination

**084691 DETECTION OF METAL CONTAMINATION IN BULK POWDERS AND GRANULES.** Inspection of free-flowing bulk solids using high-performance metal detectors is an excellent method of eliminating metallic contaminants. A system may be installed where the product is falling freely by gravity, in existing pipework, or beneath a feed hopper. Machinery protection and improvement to product quality are metal detectors' prime benefits, but they also offer a supplement to consumer protection on finished-pack inspection. The article discusses the design and operating principles of vertical fall metal detectors. (Author abstract)

## Density

**084692 PARTICLE DENSITY DISTRIBUTION IN THE FREEBOARD OF A FLUIDIZED BED.** An experimental apparatus to measure the particle density distribution in the freeboard near the surface of a fluidized bed was developed. Experiments were carried out on a scale model of an atmospheric fluidized bed combustor. The magnitude and duration of gas jets at the bed surface were also measured. The density was found to decrease exponentially with height; the rate of decrease was higher at smaller values of  $U/U_{mf}$ . The mean size of the particles

in the freeboard did not change for heights up to 36 cm. The variation with density followed the variation in heat transfer to horizontal tubes in the freeboard. A particle trajectory model was developed using the in-bed particle size distribution for particles ejected into the freeboard under the action of the gas jet. The predicted rate of change of particle density with height agreed within 20% of the experimental value when the mean values of the measured jet velocity and duration were used in the model. The model was sensitive to the jet characteristics. (Author abstract) 12 refs.

## Electrodeposition

**084693 ELECTRODEPOSITION OF CATALYTICALLY ACTIVE NICKEL POWDERS FROM ELECTROLYTES OF VARIOUS ANIONIC COMPOSITIONS.** The electrodeposition of nickel powders from different baths containing the same chemical constituents except for the anion was studied. The baths were based mainly on aqueous dilute solutions of nickel sulfate, chloride, iodide, nitrate and acetate. A detailed study was carried out to investigate the influence of these anions on the cathodic polarization curves, current efficiency, growth morphology and catalytic activity of the electrodeposited nickel powders. The characteristics tested were affected to different extents by the nature of the anion employed. (Edited author abstract) 23 refs.

**Encapsulation** See Also MONOMERS—Polymerization.

**084694 UNIFORM ENCAPSULATION OF FINE INORGANIC POWDER WITH SOAPLESS EMULSION POLYMERIZATION.** The encapsulation of inorganic powder of submicron sizes was attempted with soapless emulsion polymerization of methyl methacrylate in water in the presence of the powder. The powders used were barium sulfate and calcium carbonate. The polymerizations were initiated by potassium persulfate and by sodium bisulfite-oxygen redox reaction. The encapsulation state of the powder with the polymer formed varied considerably with the initiators used. With potassium persulfate initiator the powder surface was partially or totally covered by polymer particles, while with redox initiator under air atmosphere the powder surface was well encapsulated with a film-like polymer layer. From the differences in the encapsulation states, an encapsulation mechanism is suggested for each initiator system. Based upon this mechanism, a new encapsulation process capable of covering uniformly fine powders with a film polymer is proposed. (Edited author abstract) 14 refs.

Hasegawa, Masahiro (Tohoku Univ, Sendai, Jpn); Arai, Kunio; Saito, Shozaburo. *J Polym Sci Part A* v 25 n 11 Nov 1987 p 3117-3125.

**084695 EFFECT OF SURFACTANT ADSORBED ON ENCAPSULATION OF FINE INORGANIC POWDER WITH SOAPLESS EMULSION POLYMERIZATION.** The encapsulation of fine inorganic powder was carried out with the soapless emulsion polymerization of methyl methacrylate in water in the presence of the powder, a layer of surfactant being

adsorbed. The powder used was titanium dioxide. Surfactants added prior to the polymerization were sodium dodecyl sulfate, dodecyltrimethyl ammonium bromide, and polyoxyethylene sorbitan mono-oleate. The encapsulation state of the powder with polymer was closely related to the amount of surfactant adsorbed on the powder; and an amount of adsorption above a certain value was necessary for uniform encapsulation. (Edited author abstract) 15 refs.

## Evaluation

**084696 EVALUATION OF THE POLISHING POWER OF MICROPOWDERS FROM THE SURFACE ROUGHNESS AS DETERMINED OPTICALLY.** The polishing powers of micro- and submicro diamond and Cubonite powders of grain size 2/1 and 5/3 in machining AK6 aluminum alloy and MO6 copper are compared, using the roughness of the polished surface as determined from scattering of a light flux as a starting point. The practical results obtained provide a basis for recommending this optical method of determining surface roughness for evaluating the polishing power of the micro- and submicro powders. (Author abstract) 2 refs.

## Explosions

**084697 IGNITABILITY AND EXPLOSIBILITY OF POLYESTER/EPOXY RESINS FOR ELECTROSTATIC POWDER COATING.** A comprehensive investigation of ignitability and explosibility properties of 11 polyester/epoxy resin powders used in electrostatic powder coating has been carried out. The powders differed with respect to the ratio of polyester to epoxy, pigment type, pigment content, density and particle size distribution. The powders were tested in the closed Hartmann bomb for establishing the maximum explosion pressure and the maximum rate of pressure rise, in the open Hartmann tube fitted with the CMI electric spark generator for measurement of the minimum ignition energy, and in the 'Nordtest Fire 011' apparatus for determination of the minimum explosible dust concentration. All the powders gave approximately the same maximum explosion pressures in the Hartmann bomb, whereas the maximum rate of pressure rise decreased with increasing pigment content and particle size. Clouds in air of all the resins had quite low minimum ignition energies. (Edited author abstract) 17 Refs.

## Fabrication

**084698 REACTION OF ACTIVE URANIUM AND THORIUM WITH AROMATIC CARBONYLS AND PINACOLS IN HYDROCARBON SOLVENTS.** Highly reactive uranium and thorium metal powders have been prepared by reduction of the anhydrous metal(IV) chlorides in hydrocarbon solvents. The reduction employs the crystalline hydrocarbon-soluble reducing agent [(TMEDA)Li]<sub>2</sub>[Nap]. The resulting active metal powders have been shown to be extremely reactive with oxygen-containing compounds and have been used in the reductive coupling of aromatic ketones giving tetra-arylethenes. Reactions with pinacols have given some mechanistic insight into the ketone coupling reaction. These finely divided metal powders activate very weakly acidic C-H bonds forming metal hydrides, which can be transferred to organic substrates. (Edited author abstract) 95 refs.

**084699 GAS-SOLIDS CONTACT EFFICIENCY IN A HIGH-VELOCITY FLUIDISED BED.** The efficiency of contact between gas and solid phases in a high-velocity fluidised bed of fluidised catalytic cracking (FCC) catalyst has been measured. The technique involves the use of heated gas as a reacting tracer and detection of this hot gas by a rapid-response thermocouple. The resulting measurement indicates how much gas emerges at the outlet from the bed without having come into contact with any solid particles. This type of information has significant implications for the design and operation of commercial high-velocity systems. A simple model is used to estimate the ratio of effective to actual particle surface area in the bed, and this defines a surface efficiency. (Edited author abstract) 18 refs.

**084700 BEHAVIOUR OF LARGE JETSAM PARTICLES IN FLUIDISED BEDS.** The behaviour of segregated jetsam particles and their effect on gas flow is not well understood. This note reports observations made in large two-dimensional and rectangular beds of the effect of a significant quantity of jetsam material. The results show that piles of large jetsam particles present a gas path of lower resistance than the sand bed. This is clearly the reason for the gas maldistribution caused by the jetsam: gas flows preferentially through the parts of the distributor covered by jetsam, to form a local spout or bubble track above each jetsam pile. 8 refs.

Carter, B. (Univ of Surrey, Guildford, Engl); Ghadiri, M.; Clift, R.; Jury, A.W. *Powder Technol* v 52 n 3 Oct 1987 p 263-266.

**084701 MIXING AND SEGREGATION KINETICS IN A STRONGLY SEGREGATED GAS-FLUIDIZED BED.** The rate of approach to steady state of a gas-fluidized bed composed of a mixture of iron and glass particles was determined, starting from both initially fully mixed and initially completely segregated conditions. The data were interpreted using a model based on a pure jetsam stratum underlying a uniform stratum of mixed composition. The model allowed calculation of the average upward velocity of jetsam particles across the interface between the strata, and of the average downward velocity of jetsam particles in the upper stratum. With some exceptions, values of two parameters calculated using the two types of runs agreed well. The mean upward jetsam velocity at the interface and the jetsam descent velocity in the upper stratum were both found to be strongly increasing functions of the excess fluidization velocity. (Author abstract) 11 refs.

**084702 HIGH-PRESSURE PARTICULATE EXPANSION AND MINIMUM BUBBLING OF FINE CARBON POWDERS.** Particulate expansion and minimum bubbling parameters are measured for fine carbon powders fluidized with synthesis gas at pressures within the range  $2,070 < P < 12,420$  kPa in an industrial, pilot-scale fluidized bed. Deviations between minimum bubbling and minimum fluidization conditions increase with increasing pressure,  $P$ . The expansion index,  $n$ , decreases with increasing  $P$  and always exceeds values recommended by J.F. Richardson and W.N. Zaki for solid/liquid systems. (Edited author abstract) 42 refs.

Jacob, K.V. (Dow Chemical USA, Midland, MI, USA); Weimer, A.W. *AIChE J* v 33 n 10 Oct 1987 p 1698-1706.

**084703 MODEL FOR THE CIRCULATING FLUIDIZED BED.** A model for the hydrodynamics of

circulating fluidized beds is proposed. The model combines existing entrainment and bed expansion correlations with a system pressure balance. Starting from a knowledge of the powder size distribution, particle density, gas velocity, equipment geometry and solids inventory, the variation of voltage within the riser is predicted together with distribution of solids between the riser and supply hopper (or 'slow' bed). Qualitative trends with gas velocity and solid circulation flux show good agreement with experiment but better quantitative agreement must await the development of an improved correlation for entrainment. (Author abstract) 17 refs.

Rhodes, M.J. (Univ of Bradford, Bradford, Engl); Geldart, D. *Powder Technol* v 53 n 3 Dec 1987 p 155-162.

**084704 STUDY OF FINE PARTICLES RESIDENCE TIME IN A JETTING FLUIDIZED BED.** Experiments were carried out to study the residence time of fine particles in a 30-cm dia. laboratory fluidized bed. Fines -170 +230 mesh with an average size of 75  $\mu$ m were injected both radially and coaxially to simulate different fines recycle possibilities in an operating unit at two different bed heights and three different bed operating conditions. It was found that the transitory time of fines from the bed surface to the collecting cyclone dipleg and filter dominated the characteristic particle collection times. The true residence time in the bed is on the order of 10 to 20 s. (Edited author abstract) 8 refs.

**084705 EFFECT OF PRESSURE ON BUBBLE PARAMETERS IN GAS-FLUIDIZED BEDS.** The effect of system pressure on bubble parameters (bubble frequency, velocity and size) was determined in a 15-in dia. fluidized bed. System pressures were varied over a range of 5 to 450 psig. The effects of particle size, particle density, gas velocity and bed height on the bubble characteristics were also determined. Bubble size decreased with pressure while bubble frequency increased with pressure. (Author abstract) 18 refs.

Chan, I.H. (Inst of Gas Technology, Chicago, IL, USA); Sishla, C.; Knowlton, T.M. *Powder Technol* v 53 n 3 Dec 1987 p 217-235.

**084706 FLUIDIZATION STATE OF ULTRAFINE POWDERS.** The fluidity of submicron powders was studied in a small-scale transparent column. Powders of Ni, Si<sub>3</sub>N<sub>4</sub>, SiC, Al<sub>2</sub>O<sub>3</sub> and TiO<sub>2</sub> were smoothly fluidized when gas velocity exceeded the apparent minimum fluidization velocity. The electrical conductivity of the particles did not affect the fluidizing quality in the range of the present experiments. All the tested submicron particles formed agglomerates during fluidization. The agglomerate size and the apparent minimum fluidization velocity were dependent on species of particles and fluidizing gas. The equilibrium size of agglomerates calculated from the apparent minimum fluidization velocity and the sedimentation velocity was in the range of 70-700  $\mu$ m. However, the agglomerates of CaCO<sub>3</sub> and ZrO<sub>2</sub> were very cohesive and could not be evaluated. The primary particle size was not a proper measure for the classification of the particles. (Author abstract) 16 refs.

**084707 FLUIDIZATION BEHAVIOUR OF FINE POWDERS AND THE CRITERION OF CLASSIFICATION OF GROUP C POWDERS.** Based on the experimental curves of  $\Delta P_B - U$  of various kinds of fine powders (FCC, AN catalyst, Al<sub>2</sub>O<sub>3</sub>, alum and limestone powders) belonging to the C group of Geldart's classification, the effect of cohesive forces between the particles on fluidization behavior has been investigated. It was found that the intersection point of  $\Delta P_{B, \max}$  VS  $\text{avg } d_p$  line and  $\Delta P_B$  VS  $d_p$  line gives more precisely the boundary value of  $\text{avg } d_p$  between A group and C group particle regions, and thus the present criterion can be used for classification

of C group particles. (Edited author abstract) In Chinese. 8 refs.

**Freezing**

**084710 DETERMINING THE THERMOPHYSICAL PARAMETERS OF MEDIA THAT FREEZE.** There are changes in the phase state of pore water in a powder medium in the region of the phase-transition temperature, and this can affect all the physicochemical properties, including the thermophysical ones. In many heat-engineering calculations, one requires the values for the thermophysical parameters and the heats of phase transitions, which are used separately. The article shows how to determine the temperature dependence of the conductivity for a moist powder medium in the phase-transition region with allowance for the latent heat of the transition in the form of heat sinks in an equation having nonlinear coefficients. 5 refs.

**Granulation**

**084711 GRANULATION OF AN INSOLUBLE POWDER IN A SPOUTED BED.** Granulation of a finely ground phosphatic rock in a spouted bed has been carried out. Granule size distribution, sphericity and crushing strength have been measured against granulation time for temperatures between 80 and 140°C and concentrations of corn starch (retention agent) between 0 and 1.8 wt.%. The granule growth rate increased with increasing starch content and was not sensitive to temperature. Particle crushing strength increased with granulation time and starch content. The sphericity of the granules increased with granulation time. The elutriation rate decreased with starch content. Granule size increased exponentially with granulation time. (Edited author abstract) 7 refs.

**084713 GRANULATION OF PARTIALLY PREWETTED ALUMINA POWDERS - A NEW CONCEPT IN COALESCENCE MECHANISM.** The proposed granulation mechanism elucidates the significance of the structure heterogeneity of the granulation feed on granule growth by coalescence. The structure heterogeneity of the fine alumina powders at various water-powder ratios was investigated by moisture distribution and tensile strength measurements. The granulation characteristics were also observed in a spouted fluidized bed granulator. Experimental data support the proposed mechanism. (Edited author abstract) 30 refs.

Huang, Ching-Chung (West Virginia Univ, Morgantown, WV, USA); Kono, H.O. *Powder Technol* v 55 n 1 May 1988 p 19-34.

**084714 MATHEMATICAL COALESCENCE MODEL IN THE BATCH FLUIDIZED BED GRANULATOR.** The granule porosity and voidage saturation (the volume percentage of the voidage filled with liquid in a granule) are two factors to determine the surface moisture of colliding granules necessary for granule growth by coalescence. The structure heterogeneity of the granulation feed is able to induce a porosity reduction by colliding granules. As a result, surface moisture is formed between the colliding granules. In this study, the coalescence mechanism model for heterogeneous granulation feed was applied. A coalescence probability function and a non-dimensional model predicting granule growth rate were obtained. Employing experimental correlations, dimensional model predictions can be obtained and are in agreement with reported data. (Edited author abstract) 33 refs.

**Grinding** See Also ZINC COMPOUNDS—Spectroscopic Analysis.

**084715 FUNDAMENTAL STUDY OF DRY AND WET GRINDING FROM THE VIEWPOINT OF BREAKING STRENGTH.** The preparation of fine powders by grinding may be accomplished by either a dry or a wet process and the differences between these have been discussed. In this paper, bending tests were carried out on glass material in order to investigate the difference between dry and wet grinding. The quantitative effects of water on bending strength, and of crack propagation on glass surface, and the relationship between the bending strength and the number of cracks were studied fundamentally. As a result, it was found that the wet strength is less than the dry, the crack length in water is larger than that in air and a wet grinding process is useful from the point of view of strength of solids. ## Magnetic Field Effects

**084717 EFFECT OF UNIFORM MAGNETIC FIELD ON PACKING OF MAGNETIZABLE GRANULAR MEDIA.** The packing of magnetizable powders is strongly influenced by uniform magnetic fields. At a superficial magnetic flux density of 50 Gauss, the apparent and tapped densities of some powders (in the 50-100  $\mu$ m size range) are decreased by approx. 10 percent and approx. 20 percent, respectively. This magnetic-field-coupled packing, strongly influenced by particle size and shape, is hysteretic, in that the final packing density depends on when the magnetic field is applied during the tapping. The results suggest that a magnetic field can influence powder flows in two ways: an anisotropic inter-particle force (which directly influences cohesion) and a decrease in packing (which influences shear flow). (Edited author abstract) 21 Refs.

**084720 NONEQUILIBRIUM PLASMA IN POWDER TREATMENT PROCESSES.** A feature of the physicochemical powder treatment processes investigated by the authors is that energy is 'pumped' from the outside into a prepared gas mixture which is at a low pressure. Such systems are characterized by a high level of energy of electrons and a high concentration of excited and charged particles at a low temperature of a neutral gas. By combining such conditions, it is possible to perform some unique process of synthesis of various inorganic substances. A difficulty arising with nonequilibrium plasma-chemical processes is their optimization, for which it is necessary both to determine the internal parameters of plasma and to calculate the kinetics of physicochemical processes. Devices employing nonequilibrium plasma excited at reduced pressures can be successfully used for the production and treatment of powders of various chemical compositions. 10 refs.

**084725 PROBABILITY-STATISTICAL EVALUATION OF THE STRENGTH PROPERTIES OF DIAMOND POWDERS.** A method is proposed in this paper for predicting the conditions required for increasing the strength of diamond powders with rejection of weak grains. The method is based on a mathematical relation connecting the diamond strength distribution factors in the original and treated batches with its limiting values  $P_{li}$ , i.e., the minimum permissible strength of grains in the treated batches. In obtaining the relations it was assumed that in the original (general) totality of diamonds the static strength of the crystals is normally distributed, while the mean arithmetic value of the strength  $P_0$  and its mean square deviation  $\sigma_0$  are known. 3 refs.

**084726 PREPARATION AND CHARACTERIZATION OF MgO POWDERS HAVING  $\text{Ca}^{2+}$  OR  $\text{Ba}^{2+}$  AS SURFACE DOPANTS.** This paper presents results of experiments aimed at: (i) preparation of powdered MgO materials having monolayer amounts of CaO or BaO segregated upon their surfaces; and (ii) testing whether such monolayer-doped  $\text{Ca}^{2+}/\text{MgO}$  and  $\text{Ba}^{2+}/\text{MgO}$  materials exhibit physical and/or chemical properties indicative of the 'rumpling' favoured by computations. Chemical comparisons made between surface reactivities of  $\text{Ca}^{2+}/\text{MgO}$  and  $\text{Ba}^{2+}/\text{MgO}$  versus the pure MgO support include: liability of surface oxide ions, as manifested in ease of heterophase oxygen isotope exchange at 623-873 K, and relative activities for oxidative coupling of methane at 923-958 K. (Edited author abstract) 18 refs.

**Measurements** See Also PARTICLE SIZE ANALYSIS.

**084727 ACCURACY EVALUATION FOR METHODS OF DISPENSING POWDERS BY WEIGHT.** Batch dispensing by weight is a major operation in many technological processes; the various methods have been described but the accuracy aspects have not been fully examined. In batch dispensing, the set batch of mass is produced by feeding the material from a bunker to a weighing device (WD) set up on an automatic balance. When the mass in the WD agrees with some set value, a command is issued to halt the supply (switch off the feed), and the batch is considered as dispensed. An attempt was made to estimate the accuracy of weighed batches of powders. 2 refs.

**084728 SIMPLE LIGHT-PROBE METHOD FOR QUANTITATIVE MEASUREMENTS OF PARTICLE VOLUME-FRACTIONS IN FLUIDIZED BEDS.** An improved light probe system in conjunction with an IBM PC interfacing system and two proposed calibration techniques provides an efficient and inexpensive method for measuring the volume fraction distribution and its statistical fluctuation (standard deviation) in fluidized beds. The results suggest that traditional mechanical recorders can give misleading information for acquiring data output from a light probe. This is mainly due to the fast fluctuating character of the fluidizing system and the slow response time of many traditional recorders. 7 refs.

**084729 MECHANICAL BEHAVIOUR OF GRAPHITE POWDER.** The wear particles appearing between two solids in dry friction are thought to have a great influence on the running of a contact. To study the mechanical properties of such particles usually called a third body, cyclic shear tests were performed on precompact graphite powder with both a three-dimensional pressing machine and a direct shear box. The results provided by the two types of apparatus and their comparison with classical friction measurements are discussed with the aim of improving the understanding of dry friction mechanisms in the sense of the third body theory. (Author abstract) 6 refs.

**Mixing** See Also CERAMIC MATERIALS—Granulation; CERAMIC MATERIALS—Processing; COMPOSITE MATERIALS—Fabrication; MIXTURES—Design; POWDER METALLURGY.

**084731 MIXING OF FINELY DISPERSED MATERIALS IN REACTORS WITH A PULSED NONUNIFORM PSEUDOFUIDIZED BED.** A physical model has been developed, along with a mathematical description of the process of mixing of two and more loose components, charged in layers, with the aim of determining the parameters of air supply ( $G$ ,  $f_p$ ,  $\psi$ ), and the time of mixing required to obtain a mixture of the required quality. It has been established experimentally that mixing of finely dispersed materials in an inhomogeneous pulsed pseudofluidized layer occurs as the result of circulatory movement of the material which encompasses the entire volume of the layer and which is created by the formation and passage of gas bubbles through the layer. The physical model and the mathematical description of the process establish the correlation between the parameters that characterize the regime of inhomogeneous pseudofluidization and the kinetic mixing of the components. 6 refs.

**084732 CONTINUOUS MEASUREMENT OF DEGREE OF MIXING IN POWDER MIXER BY AN OPTICAL METHOD.** A new system has been developed to measure continuously the flow characteristics of solid particles and the degree of mixing in powder mixers. Modulated light from a light-emitting-diode is conducted onto a mixture of colored particles through a probe consisting of a pair of optical fibers, and the intensity of the reflected light from the surface of the mixture is measured continuously by a high-sensitive photometer. Five sets of the probes are installed in separate positions of a mixer vessel. The signal from the five photometers are

processed by an analog-to-digital converter and a microcomputer system. The concentration of the key component in the mixture and the degree of mixing at every moment are calculated and displayed on the video screen of the computer system. (Author abstract) 8 refs.

## Morphology

**084733 EVALUATION OF THE 'BLANKET' ALGORITHM FOR RUGGEDNESS ASSESSMENT.** A Richardson plot of an arbitrarily rugged line can be constructed by 'coating' it with a 'blanket' of increasing thickness and calculating its length from the blanket's area divided by its thickness. This algorithm was applied to lines constructed with constant and variable random frequency and random amplitude within a predetermined range. Since lines could be generated using the same parameters but different random features, the method could be tested for reproducibility and sensitivity. The method satisfies both conditions. (Edited author abstract) 7 refs.

## Oxygen Determination

**084736 BRIEF INTRODUCTION OF DETERMINATION OF OXYGEN CONTENTS IN METAL POWDERS AND NATIONAL STANDARD GB4164-84.** Several conventional and international methods for determining oxygen contents in metal powders the values obtained by these methods and their effects on technology have been described. A detail comparison has been made between the national standard GB 4164-84 'Determination of Reducible Oxygen Contents by Hydrogen in Metal Powders' and the current international and corresponding standards in various countries. GB4164-84 has the advantages of eliminating interference from carbon, wide range of applications, good efficiency of purification of hydrogen gas and rapid determination. (Author abstract) In Chinese.

## Packaging

**084737 STROEMUNGSTECHNISCHE OPTIMIERUNG EINER PNEUMATISCHEN FUELLMACHINE UND VERBESSERUNG DES WAGE-SYSTEMS.** [Optimizing the Flow Conditions in a Pneumatic Filling Machine and Improving the Weighing System]. Knowledge derived from previous basic experimental research was translated into actual practice with the design of the HSP high-speed sack packer. The results of the two-dimensional model tests were verified in two prototypes. The measurements substantially confirmed the results of the model tests. For example, for PVC powder it proved possible to double the hourly sack filling performance with the prototype HSP, while moreover the filling time, air consumption and current consumption were reduced to half the values for the type 60 FF machine. The special design of the aerating bottom enables the filling machine to be optimally adapted to whatever material it has to deal with. (Edited author abstract) In German.

**084738 DEGREES OF CRYSTALLINITY AND POLYMERIZATION OF MODIFIED CELLULOSE POWDERS FOR DIRECT TABLETING.** Modified celluloses are probably the best regarded pharmaceutical excipients for direct tableting. The degrees of crystallinity and of polymerization of 21 celluloses used in direct tableting were determined, using X-ray diffraction and viscosimetry respectively. The crystallinity of the microcrystalline celluloses varied widely from one product to another. Average degrees of polymerization were less than the usually accepted value of the 'level-off degree of polymerization'. Degrees of crystallinity of powdered celluloses were generally lower than those of microcrystalline celluloses, although some were as high as those of certain hydrolyzed samples. Degrees of polymerization of powdered celluloses did not differ as much as those of microcrystalline celluloses. The observed ranges for both parameters were wider than previously reported; the differences could be explained by structural considerations. (Edited author abstract) 38 refs.

## Permeability

**084739 VIBRATIONAL DOSING (METERING) OF HIGHLY DISPERSED POWDERS.** The process of vibrational dosing of highly dispersed powders was studied. In order to improve the effectiveness of this process, it is necessary to control the rheological properties of the powders. During the process, there are five periods of variation of the productivity of the vibrational metering device depending on the level of the powder in its receiving bunker. Clay, feldspar and talc were used as model powders. 19 refs.

Klimenko, V.P. (Acad of Sciences of the USSR, USSR); Ur'ev, N.B. *Refractories* v 28 n 1-2 Jan-Feb 1987 p 29-33.

## Permeability, Mechanical

**084740 ADVANCES IN GAS PERMEABILITY MEASUREMENTS.** The Carman-Arnell equation relates the rate of flow of a fluid through a packed bed to the pressure drop across the bed. This equation is the basis for surface area determination by permeametry. It is found that the surface area measured at sub-atmospheric pressure varies with the bed porosity, so a porosity was selected where the rate of change was at a minimum. The study suggests that, at reduced pressures, the gas flow rate is a linear function of the mean pressure. (Author abstract) 13 refs.

## Polymerization

**084742 POLYMERIZATION AND CRYSTALLIZATION BEHAVIOR OF A LARC-TPI POWDER.** The crystallization and polymerization behavior of a crystalline LARC-TPI powder at elevated temperatures have been studied. The characterization methods include differential scanning calorimetry and the measurements of inherent viscosity,  $\eta_{inh}$ , and viscoelastic properties of the fully imidized samples. The as-received material possesses an initial crystal melting peak temperature of 272°C. For the material annealed at temperatures below 320°C, a semicrystalline polymer can be obtained. On the other hand, a purely amorphous structure is realized in the samples annealed at temperatures above 320°C. (Edited author abstract) 12 refs.

Porosity See Also PARTICLE SIZE ANALYSIS; PARTICLE SIZE ANALYSIS—Measurements.

**084743 POROSITY CALCULATIONS OF MULTI-COMPONENT MIXTURES OF SPHERICAL PARTICLES.** It is shown that the relative maximum void contraction and the corresponding relative fractional solid volume are only the functions of size-ratio for binary mixtures, which can be determined experimentally. A linear analytical model, directly based on the experimental results of binary mixtures, is developed. The results show that the calculated porosities for ternary mixtures are within 8% relative error of measurements. Good agreement between the theoretical and experimental results was also obtained for Gaussian and log-normal size distributions. It is concluded that the porosity of multi-component mixtures of particles may be confidently predicted from the results of binary mixtures. (Author abstract) 23 refs.

**084744 MERCURY POROSIMETRY IN RANDOM SPHERE PACKINGS: BREAKTHROUGH PRESSURE AND PORE STRUCTURE DETERMINATION.** By using a model which accounts for the filling of all four throats connecting the central pore cavity in a random packing of spheres, good agreement between theoretical and experimentally measured pore size distributions in random packings of spheres has been obtained. Even after a central pore cavity has been filled through the largest throat in the face of a tetrahedron, some of the total pore volume in the tetrahedron, some of the total pore volume in the tetrahedron will not be filled until higher pressures associated with the smaller throats are reached. Approximately 11% of the total pore volume is observed

as this throat filling process. The error associated with the use of the independent domain theory appears in terms of a broader calculated pore size distribution in the region of central cavity filling. 18 refs.

**084746 MERCURY POROSIMETRY OF ORDERED SPHERE COMPACTS: INVESTIGATION OF INTRUSION AND EXTRUSION PORE SIZE DISTRIBUTIONS.** In this work, the possible use of both intrusion and extrusion for pore structure characterization has been investigated. Submicron monosize spherical particles of silica and yttrium hydroxycarbonate were synthesized and ordered compacts of these powders have been prepared. Mercury porosimetry tests on the high-density compacts (typically 68-70% of sphere density) have shown the presence of two pore peaks for intrusion and extrusion with the exception of one compact. Comparisons of intrusion pore sizes with the theoretical sizes of the constrictions for ordered sphere packings have shown reasonable agreement. Similar comparisons between the sizes of cavities in sphere packings and the extrusion pore sizes did not show the same agreement. Results for one sample did not show a distinct extrusion pore size even at large pore sizes, most probably due to the domination of mercury extrusion by few large pores in the sample. For all other samples, the extrusion pore sizes were close to the actual sphere size and the extrusion was probably dominated by a few vacant sphere sites in the ordered structures. The results have shown that the possibility of using extrusion data for pore body size distribution determination is in doubt. The presence of few larger pores in the porous body may dominate the extrusion process and can cause inaccurate pore size information. (Edited author abstract) 25 Refs.

**084748 EFFECT OF TEXTILE AUXILIARIES ON THE FREE-FLOWING CELLULOSE POWDER.** The effect of textile auxiliaries on the bulk density and water vapor sorption of cellulose powder prepared from fiber waste from viscose manufacturing is studied. It is shown that treatment of the cellulose powder with textile auxiliaries leads to an increase in its free-flowing properties and to a considerable improvement in the quality of the product obtained. A composition based on S-9 mineral oil and an added emulsifier, which reduces the bulk density of the cellulose powder by 46-57%, is the most effective agent. 4 refs.

Agafnova, L.L.; Glavochevskaya, R.A.; Panova, L.N.; Egorova, R.V.; Dmitriev, V.A. *Fibre Chem* v 19 n 2 Mar-Apr 1987 p 111-113.

**084749 AGITATION IN DRY MATERIAL FEEDING.** Keeping dry materials flowing from metering devices into processing systems has long been a problem. Dry materials tend to be sticky, to bridge over the metering screw, or to pack in the hopper. This can cause discrepancies in feeding accuracy, consistency, and uniformity. The gentle massaging action of flexible wall feeders is a solution to the problems generally associated with other agitation mechanisms.

Anon. *Powder Bulk Eng* v 1 n 12 Dec 1987 p 28-31.

**084750 GRAINS OF HOPE.** One aim of the present Science and Engineering Research Council (SERC) Specially Promoted Programme (SPP) in particulate technology is to bring academic scientists and industrial engineers together. To this end, the SPP has directed the resources at its disposal towards three main areas of investigation: particle formation, solid-liquid phenomena and dry solids handling. It aims to 'radically improve our processing ability' through a proper understanding and utilization of process control parameters such as particulate characteristics. The flow behavior of a powder, be it dry, wet or suspended, when subjected to external stresses, is a predictive problem of immense complexity. We can identify three distinct levels of characterization which, if successfully researched and described, could in principle lead to a complete prediction of powder flow behavior for engineering design.

Woodcock, Les. *Process Eng (London)* v 68 n 10 Oct 1987 p 41-43.

**084751 HYDROCHEMICAL PREPARATION OF FINE PRECIOUS METAL POWDERS.** The importance of fine precious metal powders for electronic material applications has spurred development of precipitation methods from aqueous and organic media. Three systems in particular are of interest: the in-situ precipitation of gold crystals from a loaded organic phase via an intramolecular redox reaction mechanism; the precipitation of palladium from loaded organic solvents by direct hydrogen reduction; and the precipitation of platinum and palladium powders from aqueous chloride solutions by hydrogen reduction. The particle size and powder morphology of the precipitates are related to the nucleation mechanism (homogeneous or heterogeneous) and the particle-particle and particle-solvent interaction. (Author abstract) 30 refs.

Demopoulos, G.P. (McGill Univ, Montreal, Que, Can); Pouskoulleli, G. *J Met* v 40 n 6 Jun 1988 p 46-50.

**084752 MATHEMATICAL ANALYSIS OF THE MILLING OF MINERAL FERTILIZER POWDERS.** A fundamental problem in the theory and practice of compressing mineral fertilizer powders is the development of methods of calculating the density of the cake formed and the milling power parameters under specific conditions and roller operation programs. The authors have investigated a two-dimensional Maxwell viscoelastic equation in a section  $\Omega$  of the compression zone. The authors also set up an algorithm for solving this equation by successive approximations in which a linear system of equations is solved at each step. For the first approximation, they developed a program of 300 commands in FORTRAN that solves an elliptical equation for  $u$  by the

method of finite elements and permits the calculation of the stress on the roller and the overall characteristics of the process: the densification coefficient, the force on the roller, and the power consumed in driving the press. The starting data needed to make a mathematical analysis of the process are given.

**Production** See Also ALUMINA—Hydrated; METALLIC COMPOUNDS—Production; POWDER METALLURGY—Compacting; POWDER METALLURGY—Iron; SILICON CARBIDE—Synthesis.

**084753 STRUCTURE OF METAL POWDERS PRODUCED BY ELECTROEROSION DISINTEGRATION IN GRANULATORS.** It is demonstrated that electroerosion (EE) disintegration is a process enabling metal powders to be obtained composed of spherical particles ranging in size from about 0.01 to about 100  $\mu\text{m}$ . During EE disintegration metal experiences local melting by electrical discharges in a dielectric liquid; as its boiling point is reached, a spray of macroscopic molten metal droplets is produced in an explosive manner, which are rapidly cooled in the surrounding liquid. In the production of a metal powder by the EE disintegration of a metal in a granulator all the conditions are spontaneously created necessary for obtaining an ultrafine-grained crystal structure in the material of the powder, so that it is not necessary to introduce special nucleating inoculant additions into the metal. 13 refs.

Fominskii, L.P. (Tulacherm Scientific Production Assoc, USSR); Levchuk, M.V.; Tarabrina, V.P. *Sov Powder Metall Met Ceram* v 26 n 4 Apr 1987 p 273-277.

**084754 FORMATION AND GROWTH MECHANISM OF POROUS, AMORPHOUS, AND FINE PARTICLES PREPARED BY CHEMICAL VAPOR DEPOSITION. TITANIA FROM TITANIUM TETRAISOPROXIDE.** The formation and growth mechanism of porous, amorphous, and fine particles were investigated.  $\text{TiO}_2$  particles were produced in a tubular flow reactor by a chemical vapor deposition technique using titanium tetraisopropoxide as a starting material at low temperatures (573-973 K) and atmospheric pressure. Prepared particles were of submicron size and had large surface area (as large as  $270 \times 10^3 \text{ m}^2/\text{kg}$ ). According to the proposed mechanism, reactions begin on the reactor wall and then the primary particles form in the gas phase by chemical reactions. The primary particles collide, coalesce with each other and grow. However, significant experimental deviations from the Brownian collision and coalescence theory imply that other processes, such as the surface reactions on the particle, play an important role in the growth, in addition to coalescence. Intraparticle reactions decreased the surface area by filling the pores. (Author abstract) 19 refs.

Kirkbir, Fikret (Univ of Tokyo, Tokyo, Jpn); Komiya, Hiroshi. *Can J Chem Eng* v 65 n 5 Oct 1987 p 759-766.

**084755 MAKING POWDERS.** As end use demands on powder (for example, microelectronic and superconductivity applications) become more pressing, the demands for understanding precipitation mechanics become more pressing. The paper demonstrates the current state of the powder precipitation. The nature of powders depends on nucleation and growth. Both nucleation and growth share supersaturation as a common driving force. Sometimes applying steam to a solution causes precipitation. Adding a component in which the solute is insoluble also causes supersaturation. The author reviews heterogeneous and secondary nucleation, particle growth and structure, and, finally, network growth of the powder precipitates. 6 refs.

Ring, Terry A. *CHEMTECH* v 18 n 1 Jan 1988 p 60-64.

**084756 LEYBOLD IN FOREFRONT OF METAL POWDER PRODUCTION TECHNOLOGY.** The Vacuum Process Engineering Division of Leybold AG in Hanau, Germany, has been designing and manufacturing special metallurgical plants for metal powder production

for more than 20 years. Over this period the company has developed sophisticated inert gas atomization systems, centrifugal atomization processes for ceramic-free metal powders, and complete powder handling and treatment systems. (Author abstract)

Williams, Bernard. *Met Powder Rep* v 43 n 6 Jun 1988 p 405-408.

**084757 PRODUCTION OF METAL POWER FROM RAPIDLY SOLIDIFIED DUCTILE RIBBONS.** Ductile metallic ribbons have been reduced into small particles by a blade cutter mill designed to cut and slash the ribbons. The resulting powders are suitable for subsequent P/M processing. This batch process and the results obtained with a Zn-20.5Al-0.7Cu alloy are described. (Author abstract) 5 refs.

Gelinas, C. (Laval Univ, Ste.-Foy, Que, Can); Angers, R.; Pelletier, S. *Mater Lett* v 6 n 10 Jun 1988 p 359-361.

**084758 EVALUATION AND CONTROL OF PARTICLE PROPERTIES IN AEROSOL REACTORS.** The production of powders by aerosol routes spans a wide range of operating temperatures depending on the type of aerosol reactors used. The dominant mechanism of particle growth and evolution depends highly on the rate at which the reactions producing the condensable species are carried out. Numerical solutions of the discrete-sectional aerosol general dynamic equation that accounts for the interactions of the discrete clusters were obtained for conditions representative of the different types of aerosol reactors used for powder production today. Simplified reaction and coagulation equations that give fast and useful prediction of the evolution of aerosols associated with chemical reactions were derived, and a simple reaction-coagulation model was developed. The effects of reaction rate, initial vapor concentration, residence time, seed particles, and temperature profile on the properties of fine particles produced by gas-phase chemical reactions were evaluated using both models. Results show good agreement between the two. (Author abstract) 18 refs.

Wu, Jwang Jin (California Inst of Technology, Pasadena, CA, USA); Nguyen, Hung V.; Flagan, Richard C.; Okuyama, Kikuo; Kousaka, Yasuo. *AIChE J* v 34 n 8 Aug 1988 p 1249-1256.

**084759 PROPERTIES OF  $\text{ZrO}_2\text{-Al}_2\text{O}_3$  COMPOSITE POWDERS PREPARED FROM Zr-Al METALLO-ORGANIC COMPOUNDS.** Zr-Al metallo-organic compounds (zirconaluminates), having  $(\text{CH}_2)_4\text{COOH}$ ,  $(\text{CH}_2)_6\text{CH}_3$  and  $(\text{CH}_2)_7\text{NH}_2$  as the organofunctional groups, were treated preliminarily by: (1) spray-drying, (2) gelation of addition of 10%  $\text{NH}_4\text{OH}$  aqueous solution followed by spray-drying, and (3) rotary evaporation under a reduced pressure. After the treatment, they were heated in air to prepare  $\text{ZrO}_2\text{-Al}_2\text{O}_3$  composite powders. The IR and DTA profiles for the treated compounds indicated that the procedures modified the structures for the zirconaluminates. The stability of tetragonal  $\text{ZrO}_2$  for the  $\text{ZrO}_2\text{-Al}_2\text{O}_3$  composite powder was dependent on the modification in the structure for the zirconaluminates. ## Pyrolysis

**084760 ESTIMATION OF FORMATION MECHANISM OF SPHERICAL FINE  $\text{ZrO}_2\text{-SiO}_2$  PARTICLES BY ULTRASONIC SPRAY PYROLYSIS.** Spherical fine  $\text{ZrO}_2\text{-SiO}_2$  (1:1) particles were synthesized from a hydrolyzed solution of  $\text{Si}(\text{OC}_2\text{H}_5)_4$  and  $\text{ZrOCl}_2 \cdot 8\text{H}_2\text{O}$  by ultrasonic spray pyrolysis. The formation mechanism of the particles is discussed. All of the particles identified as t- $\text{ZrO}_2$  and amorphous  $\text{SiO}_2$  with an atomic

order dispersion were spherical and mainly of diameter 0.8 to 1.0  $\mu\text{m}$ . It is estimated that the three-dimensional ladder siloxane chains containing an equimolar  $\text{Zr}^{4+}$  homogeneously dispersed were formed by hydrolysis. An atomized droplet converted into an isolated  $\text{ZrO}_2\text{-SiO}_2$  (1:1) particle without aggregation. (Edited author abstract). 22 Refs.

**084761 RHEOLOGY OF AQUEOUS DISPERSIONS OF ALUMINA, TITANIA AND MIXTURE OF ALUMINA AND TITANIA POWDERS.** The electrophoretic mobility and rheology of alumina, titania and alumina/titania powder mixtures (ratio of alumina:titania 1:2 and 2:1) were investigated in aqueous suspensions in the pH range 3 - 10. The results suggest that the electrophoretic mobility of the individual powders is independent of the particle concentration, but the electrokinetic behavior of the powder mixture depends upon the concentration of the individual constituents. The rheology of all the suspensions is charge related and while alumina and alumina/titania (ratio 2:1) flocculate at pH 9.0 both titania and alumina/titania (ratio 1:2) form low viscous dispersions. (Edited author abstract) 17 refs.

**084765 ON THE DIVERGENCE PROBLEM IN**

**CALCULATING PARTICLE VELOCITIES IN DILUTE DISPERSIONS OF IDENTICAL SPHERES: II. EFFECT OF A PLANE WALL.** The authors consider a dilute random dispersion of identical spheres sedimenting slowly in a viscous fluid toward a horizontal plane wall. This wall imposes the return flow and yields the usual result for the effect of long-range interactions on mean velocity. Since the usual method of imposing return flow leads to the divergence of the variance of velocity, they used this method to calculate the covariance matrix. Lengthy but straightforward analytical integration and algebraic manipulation yield a diagonal matrix whose entries are finite when the test sphere is a finite distance  $z$  from the plane. The trace of this matrix is the variance of velocity. This vanishes as the solids fraction approaches zero, confirming a postulate of the Pickard-Tory model for sedimentation. However, its linear dependence on  $z$  seems unphysical and additional terms should be derived. Additional boundaries may also be necessary. (Edited author abstract) 23 refs.

**084766 EFFECT OF RIGID INCLUSIONS ON THE SINTERING OF GLASS POWDER COMPACTS.** The effect of rigid inclusions on the sintering of glass powder compacts has been investigated at 600°C. The densification rates show good agreement with the rule of mixtures for inclusion volume fractions of  $\leq 0.1$ . The transient stresses generated during sintering by the presence of the inclusions were evaluated from the sintering data. Below inclusion volume fractions of approximately 0.12, the results are in excellent agreement with Scherer's theory for viscous sintering with rigid inclusions. At higher inclusion volume fractions, interactions between the inclusion particles lead to large deviations from theoretical predictions. (Author abstract) 13 refs.

**Size Determination**

**084767 ACCURACY OF DUAL PARAMETRIC DISTRIBUTION FUNCTIONS USED FOR THE DESCRIPTION OF PARTICLE SIZE DISTRIBUTIONS.** The determination of particle size distribution of powders is generally carried out by sieve analysis in which the particles are separated into six or ten fractions regarding their sizes. The analysis itself is often laborious, time consuming and therefore gratuitous. Efforts were made to lessen the number of fractions without a significant decrease of accuracy and reproducibility of particle size distribution values. The application of dual parametric distribution functions was investigated both theoretically and practically, the latter by using experimentally determined data. As a result, the selection and number of fractions are recommended and the application of multi-stage cyclone instruments is proposed. (Author abstract) 9 refs.

**084768 MOLECULAR MOTIONS FROM TWO-DIMENSIONAL NMR OF POWDERS: COMPARISON OF ROTATIONAL JUMPS AND DIFFUSIVE REORIENTATIONS.** With the two-dimensional (2D) exchange NMR experiment on polycrystalline or amorphous solids it is possible to study reorientations in the slow motion limit. Anisotropic interactions lead to 2D powder spectra exhibiting characteristic singularities ('ridges'). From such a powder spectrum the relative

orientations of a coupling tensor at the beginning and at the end of the mixing time can be measured without reference to any model of reorientation. The method is demonstrated for hexamethylbenzene and linear polystyrene. (Author abstract) 32 refs.

**084769 MATHEMATICAL JUSTIFICATION OF THE USE OF IR TRANSMISSION SPECTROSCOPY FOR THE QUANTITATIVE ANALYSIS OF SURFACE-TREATED POWDERS.** Measuring the IR transmission through a loosely packed powder layer offers a cheap and experimentally simple method for the quantitative and qualitative analysis of surface-treated powders. It is, however, practically impossible to obtain a perfectly smooth and even powder layer - a fact that introduces large errors in the quantitative determination. To cope with this problem, one derives an equation, by means of which it is possible to carry out the determination irrespective of the layer-thickness variations. The equation is based on the use of an 'internal thickness standard.' The theory is illustrated with, and supported by, a series of determinations of a silane coupling agent on a phlogopite powder. (Edited author abstract) 11 refs.

**084770 ANALYSIS OF INORGANIC POWDERS BY TIME-WAVELENGTH RESOLVED LUMINESCENCE SPECTROSCOPY.** A spectrometer for measuring time-wavelength resolved luminescence spectra was constructed. A gated integrator was used for time resolution. Solid samples of  $\text{CaWO}_4$ ,  $\text{CaMoO}_4$ ,  $\text{SrWO}_4$ , and  $\text{SrMoO}_4$  were excited at room temperature by an excimer laser at 193 and 248 nm. The substances examined showed first order decay kinetics and the spectra were broad, featureless Gaussian bands. The luminescence spectral envelope was described by the parameters lifetime, peak maxima, peak half-width, and intensity factor. Data reduction was carried out by using a linear algebra construct and simplex optimization. The algorithm was evaluated with synthetic data. (Edited author abstract) 17 refs.

**084771 DETERMINATION OF PARTICLE SIZE IN POWER BY SCATTER CORRECTION IN DIFFUSE NEAR-INFRARED REFLECTANCE.** Diffuse near-infrared reflectance spectroscopy has traditionally been an analytical technique for determining chemical compositions in a sample. The authors focus on light scattering effects and their ability to determine the mean particle sizes of powders. The reflectance data of NaCl, broken glass, and sorbitol powders are linearized and submitted to the Multiplicative Scatter Correction (MSC), and the ensuing parameters are used in subsequent multivariate calibrations. The results indicate that particle size can, to a large degree, be determined from NIR reflectance data for a given type of powder. Up to 99 percent of the partial size variance was explained by the regression. (Edited author abstract). 19 Refs.

## Stresses

**084773 SHEAR PROPERTIES OF UNIAXIALY PRE-CONSOLIDATED POWDER BED - NON-UNI-FORMITY OF THE SHEAR STRESS ACTING ON THE SHEAR PLANE.** Failure properties of a powder bed have been widely obtained by the shear tests on the basis of Jenike's method. A special feature of Jenike's method is that a powder bed has been sheared in pre-consolidating before the shear test (pre-shearing). Therefore, it is presumed that the failure properties of the shear-consolidated bed pre-sheared on the basis of his method differ from the properties of the uniaxially consolidated bed. Although a uniaxially consolidated bed is often handled in powder operation, the failure properties of the bed have been scarcely discussed since the experimental results lack reliability. In this paper, a new experimental method is presented to obtain the exact failure properties for a uniaxially consolidated powder bed. Further, the results obtained by Jenike's tester are compared with those by our tester. (Author abstract) 13 refs.

## Surface Measurement

**084775 RAPID SURFACE AREA DETERMINATION VIA NMR SPIN-LATTICE RELAXATION MEASUREMENTS.** In this work, a theoretical and experimental approach has been developed for measuring the surface area of both solid powders and porous solids. Spin-lattice relaxation measurements were made of adsorbed water at 20 MHz and 303 K. Materials studied included three Cab-O-Sil fumed silica powders and three controlled pore glasses with various water contents. The variation of the observed spin-lattice relaxation decay time was found to be linear with both the solids concentration and specific surface area, as predicted by the theory. (Edited author abstract) 19 refs.

## Surfaces

See Also FLOW OF FLUIDS—Packed Beds; SURFACE ACTIVE AGENTS—Adsorption.

**084777 SURFACE AREA DETERMINATION VIA NMR: FLUID AND FREQUENCY EFFECTS.** The use of NMR spin lattice relaxation measurements has been proposed as a tool for the determination of specific surface area. The use of this approach was demonstrated using relaxation measurements of water at 20 MHz for two materials with similar surface chemistry. In principle, the surface-enhanced spin lattice relaxation rate is a function of proton frequency, fluid, temperature and surface chemistry. This paper, describes relaxation measurements at 303 K using a range of fluids (water, methanol, ethanol, cyclohexane) at two proton frequencies (20 and 300 MHz) for samples with different surface areas from three different porous solid groups (controlled pore glass, mixed ester cellulose membranes and carbon blacks). Surface areas studied were in the range of 4.4 to 179.0 m<sup>2</sup>/g. A three-fold increase in the sensitivity of the surface area determination is noted when the frequency is decreased from 300 to 20 MHz. In general, surface area sensitivity increases with fluid type as (cyclohexane < water < methanol < ethanol). (Edited author abstract) 11 refs.

**084778 GEOMETRY FOR CHARACTERIZING FRACTURED PARTICLE SHAPE.** In the physical model of particle formation by the catastrophic failure of a brittle solid, it is postulated that cracks sequentially form the surfaces of the fragments and that the resulting particles may be characterized by faces, edges and points. Using this simple model and several apoditic observations, three equations are derived that relate the number of points on a particle to the number of edges and faces on that particle surface. It was found that the number of points on the surface of a particle is always even, there are 50 percent more edges than points and the number of faces is 2 plus half the number of points. Unusual or forbidden shapes were found that are both rare and tend to disappear on further size reduction, and, moreover, are characterized by pairs of multiply connected points. Moreover, because a fragment is one of a very large number of particles, it will have traces (faces) of other particles on its surface, and its shape will be complex. Finally, using a point counting system, a particular characterization system for angular particles is proposed. (Author abstract) 9 refs.

**084780 SYNTHESIS OF HYDROUS SnO<sub>2</sub> AND SnO<sub>2</sub>-COATED TiO<sub>2</sub> POWDERS BY THE HOMOGENEOUS PRECIPITATION METHOD AND THEIR CHARACTERIZATION.** The article concerns a new method to prepare fine ceramic powders coated with other kinds of substances. These powders are useful because it is possible to make a new class of powder with two different properties. For example, SnO<sub>2</sub>-coated TiO<sub>2</sub> powder has the shielding power and UV absorption of TiO<sub>2</sub> and the electrical conductivity of SnO<sub>2</sub> and is of practical interest as a filler for plastic films. The homogeneous precipitation method is one of the best methods to control the pH and to form pure and dense precipitates, because it produces a precipitant slowly in the solution. This paper deals with the synthesis of SnO<sub>2</sub>-coated TiO<sub>2</sub> powders using the homogeneous precipitation method as a coating process. The powders have been characterized with scanning electron microscopy (SEM), thermogravimetry, differential thermal analysis (TG-DTA) and X-ray diffractometry (XRD). Electrical conductivities were also measured. 12 refs.

## Testing

**084781 TESTING OF REFRACTORY METAL POWDERS.** Engineering components and other products made from metal, ceramic and plastic powders can be defined by specific parameters, but the powders from which they are fabricated cannot be so easily defined. In the case of metals it is particularly relevant, and a range of physical and chemical properties have to be tested for and equated to determine the properties of the ultimate powder metallurgy processed end products. This review of testing procedures covers powder metallurgy products which are predominantly based on refractory metals. The greatest tonnage of these are derived from tungsten and molybdenum, but reference is also made to tantalum and hard metals.

## Thermal Effects

See HELIUM—Fluid Dynamics; SILICON NITRIDE—Composition Effects.

## Thermodynamic Properties

**084782 THERMODYNAMIC CHARACTERISATION OF MICROCRYSTALLINE AND MICRO-FINE CELLULOSE POWDERS.** Cellulose produced by different processes (Spray dried and comminuted) have been characterized by low temperature (77K) nitrogen adsorption to determine the specific surface areas, micro- and meso-porosities together with the thermodynamic properties of the Polanyi surface potential and heat (enthalpy) of adsorption. These physico-chemical and thermodynamic parameters are then correlated with the physico-mechanical properties of compactability to indicate the bonding strengths of microcrystalline and micro-fine celluloses. (Author abstract) 11 refs.

Stanley-Wood, Nayland (Univ of Bradford, Bradford, Engl). *Part Charact* v 4 n 3 Sep 1987 p 106-111.

## Transport Properties

**084783 INTRINSIC-TRANSPORT MODEL FOR SOLID-SOLID REACTIONS INVOLVING A GASEOUS INTERMEDIATE.** A model has been developed for solid state reactions between powders in pellets or beds of reacting mixtures where the rate-limiting step is diffusion of a gaseous intermediate within the pore space (called intrinsic transport). The basis of the model is a network of expanding reaction cells, each centered on a particle of the reactant which gives rise to the gaseous intermediate. The partial pressure of the intermediate decreases from the equilibrium value at the surface of the central particle to zero at the reaction front of the cell due to reaction with the other solid reactant within the cell volume. The rate constant for an intrinsic transport controlled reaction is related to physical properties of

the system. A partial pressure of the intermediate on the order of  $10^{-4}$  to  $10^{-10}$  atm is sufficient to sustain solid state reactions at commonly observed rates. (Edited author abstract) 17 refs.

Wynnycky, J.R. (Univ of Waterloo, Waterloo, Ont, Can); Ruskin, W.J. *Mettall Trans B* v 19B n 1 Feb 1988 p 73-81.

## Transportation

**084784 TRANSPORTATION OF POWDERS USING A LINEAR MOTOR DEVICE.** The theory of linear motors has been formulated for both magnetic and non-magnetic reaction plates and criteria established to assess their performance. The predominant mechanism involved in the transportation of ferromagnetic powders cannot be the same as that in a motor device, because basic calculations show that the induced currents in the particles at 50 Hz are small. Instead, the ferromagnetic particles seem to follow the movement of the travelling magnetic field itself. This paper illustrates the motion of the particles along a linear motor device and also reviews the experimental work done previously, especially that associated with powder cleaning devices. Areas of future research work to be followed are discussed and possible new industrial applications mentioned. (Edited author abstract) 13 refs.

## Wear

**084785 REVIEW OF ATTRITION AND ATTRITION TEST METHODS.** The sources of attrition during the use of particulate materials are described and the mechanisms which cause breakdown are discussed. Techniques for testing the susceptibility of particles to attrition aim either to characterize and compare attrition of different materials or to predict particle behavior during powder use. The majority involve some form of mechanical means for inducing attrition under standard if undefined conditions. The mechanical tests fall into two categories, namely single particle and multi-particle. The multi-particle tests more closely relate to powder use but they are primarily empirical in nature whereas the single particle tests enhance the understanding of particle breakage but are difficult to compare with attrition observed in practice. The use of tests for predictive purposes currently presents difficulties, especially under diverse conditions of application. (Edited author abstract) 103 refs.

## Wear Resisting

**084786 WEAR-RESISTANT POWDER MATERIALS WITH INTERMETALLIC HARDENING. I. NONPOROUS MATERIALS FOR ANTIFRICTION PURPOSES.** The authors suggest the following principles of designing wear resistant materials: ensuring a homogeneous and balanced structure consisting of three phases where the base (the matrix) is the elastoplastic phase, then there are wear-resistant inclusions uniformly distributed throughout the bulk of the grains and inclusions having a laminated structure uniformly distributed along the grain boundaries; the material of the abradant is single-phase material with greater microhardness than the matrix; the structure of the material does not change in the process of friction. The results of the investigations confirm the possibility of predicting the structure and properties of wear-resistant powder materials with intermetallic hardening, and also of correcting the chemical composition in dependence on the operating conditions of the material. 13 refs.

**084787 SMALL SCALE COMBINED HEAT AND POWER SYSTEMS. PART 1: TECHNICAL ASPECTS AND GOVERNING REGULATIONS.** The Lambeth Small Scale Combined Heat and Power 3-Year Demonstration Project is being undertaken by the Centre for Energy Studies which is part of the Polytechnic of the South Bank, London. The primary objective of the project is to show that where a demand exists for both heat and electric be maximized and consequently fuel costs to be reduced. The search for a suitable location for the demonstration project involved the analysis of heat and electricity consumption in a wide range of buildings throughout the London Borough of Lambeth. For this particular project it was necessary to find a location which offered accommodation for demonstration and seminar purposes, as well as having a suitable annual energy profile. The British Home and Hospital at Streatham met all these requirements and this paper has been produced to provide an introduction to the technology and application of micro CHP in a selected location.

Rufford, George (Energy & Business Management Consultancy, Woodbridge, Engl). *H&V Eng* v 59 n 675 p 10-13.

**084788 PHOTOVOLTAIC POWER GENERATION TECHNOLOGY IN FUTURE URBAN LIFE.** A photovoltaic power generation system can be recommended as a leading member for the dispersed power system because of its nature, e.g., simple system, clean energy, easy handling, maintenance free, etc. It cannot be forgotten for the urban construction of the future. The author explains about present status and activity of photovoltaic power generation in accordance with such a viewpoint. Further contents are the statistics of solar cell production and its cost, and the technology flow regarding cell production processes and applications, future aspects of conversion efficiency improvement of various kinds of solar cells, a principle system configuration diagram, system classification, etc. Trends in the commercialization toward the introduction to a future city and problems on electric power network at the introduction are also mentioned. (Edited author abstract) In Japanese. 15 refs.

**084789 FULL-SCALE TESTING OF THE LENIN-GRAD METAL WORKING PLANT 1200 KtsS-1 CONDENSER OF THE 1200 MW POWER-GENERATING UNIT AT KOSTROMA CENTRAL POWER STATION.** Thermal tests were conducted on the LMZ 1200 KtsS-1 condenser to determine its actual performance characteristics and to check operational efficiency of the tube bundles. The LMZ-1200 KtsS-1 sectional condenser group is designed to condense exhaust steam from the LMZ K-1200-240 turbine and it consists of four condensers connected with respect to cooling water in two parallel groups in each of which the two condensers have the cooling water connected in series via an intermediate water box. The full-scale thermal testing of the LMZ 1200 KtsS-1 condenser confirmed the high design characteristics at design cooling water temperature ( $12^{\circ}\text{C}$ ) and above. At c.w. temperatures below  $12^{\circ}\text{C}$  the actual characteristics were found to be inferior to the design ones but not to the characteristics of other types of Soviet condensers. 2 refs.

**084790 NEUER WÄRMEEKRAFTPROZESS FÜR DIE NUTZUNG VON NIEDERTEMPÉRATURWÄRME.** [New Thermal Power Process for the Utilization of Low-temperature Heat]. The working principle and the motion equation of the expansion and compression strokes of a new thermal power process, which is similar to the Stirling one, are described in this

paper. The calculated motion operation is shown in a p,V-diagram. In this double-acting thermal power process, an isothermal operating process is realized with good approximation. The thermal energy is transferred to a working gas by means of a working liquid during the expansion stroke. The cooling during the compression of the working gas is effected by a counterstroke to the expansion in a second working cylinder in the same way by means of a working liquid. Both gas chambers are separated by a movable liquid column. With the aid of the operating process this liquid is set into oscillation. The oscillation can be converted into electric energy. The non-operational pressure of the working gas can be varied within a wide range of boundaries. The sealing of the gas is problem-free. For operating the engine, low-temperature heat - either from solar collectors or from waste process heat - is also particularly suited. (Edited author abstract) In German.

**084791 MAIN STAGES IN THE DEVELOPMENT OF THE POWER INDUSTRY OF KAZAKHSTAN DURING THE LAST 70 YEARS.** Industry was very little developed in Kazakhstan in the prerevolutionary period. The capacity of all the power stations in prerevolutionary Kazakhstan was no more than 2.5 MW, with annual generation of power of 1,300,000 kWh, which was 2 to 3 times less than the requirement today for one mechanised state farm. Significant development of the power industry in the republic began in 1928 when, in accord with Lenin's GOELRO plan, the first large hydro station was built and put into service; this was the Khariuzovsk Hydro Station with a capacity of 3 MW, which is still operational today. At the start of the first five-year plan overall capacity of the Kazakhstan power stations had reached 9.0 MW, some 7,000,000 kWh being generated. In prewar 1940 capacity of the Kazakhstan power stations was already 224 MW and the power generated 630,000,000 kWh. The paper provides a historical perspective of the development of the power generation facilities in Kazakhstan.

## Control

**084792 AUTOMATIC GENERATION CONTROL FOR HYDRO SYSTEMS.** The authors present the decision of an automatic generation control (AGC) system implemented with digital computers that periodically sample tie-line real power flows, line frequency, and generator power outputs. These analog signals are measured at 2-5 intervals and combined with desired interchange to obtain the area control error (ACE). The ACE digital quantity is allocated to regulating hydro turbines and transmitted via telemetry to the remote terminal units (RTU). The RTUs convert the raise/lower megawatts (MW) into timed relay contact closures to the governor which result in wicket gate open/close movement to change the generator output power. The output power of each generator is monitored by the digital AGC, which closes a feedback loop around the governor-turbine-generator to assure that the desired power level is attained. The feedback loop design, which is essentially a sampled-data control, is described. Additional feedback loops due to the ACE and load regulation are also analyzed. A method for allocating water usage between reservoirs on a generator command-time basis is presented. The theoretical designs are verified by online measurements. 6 refs.

**Pumps** See Also ELECTRIC POWER PLANTS—Thermoelectric.

**084794 APPLICATION OF CENTRIFUGAL PUMPS FOR POWER GENERATION.** The fact that centrifugal pumps can be used as turbines has been known for over half a century, but only limited use has been made of this knowledge. In most cases this has been due to ignorance. Although water turbines for plant power recovery situations are generally uneconomical, it would at times be viable to use pump turbines. Characteristics of pumps are freely available from pump manufacturers, but their characteristics as pump turbines are not. This article provides some basic ground rules and examples of possible applications. (Edited author abstract) 9 refs.

**084795 MODIFIED REFRIGERANT COMPRESSOR AS A RECIPROCATING ENGINE FOR SOLAR THERMAL POWER GENERATION.** The prime mover of a small solar thermal power generation system can be either a turbine or a reciprocating engine. In this paper a case is made for the use of a reciprocating engine instead of a turbine. A new design of valves is described which results in an extremely simple reciprocating engine. It is argued that the efficiency of such an engine would be at least as good as that of a comparable turbine. A one-ton refrigerant compressor was modified to incorporate the valves proposed in order to run it as an engine. The engine was run on compressed air and the pressure-time diagram of this engine has been analyzed to evaluate the performance of the new valves. The present engine is compared with a similar engine developed by the Thermo Electron Corporation, U.S.A. (Author abstract) 4 refs.

**084796 EARLY EXPERIENCE WITH SOLAR ELECTRIC GENERATING STATION 1 AT DAGGETT, CALIFORNIA.** The solar field comprised of 71,680 square meters of Luz parabolic trough line-focus solar collectors, supplies thermal energy at about 307°C (585°F) to the thermal storage tank. This energy is then used to generate saturated steam at 3.79 MPa and 247°C (550 psia and 477°F), which passes through an independent natural gas-fired superheater and is brought to 416°C (780°F) superheat. The SEGS I solar electric plant is performing well in its startup year of operation. Placed in service on schedule in 1984, the plant is producing electricity with a high degree of reliability.

## USSR

**084797 POWER INDUSTRY IN THE 12TH FIVE-YEAR PERIOD.** In the decisions of the 27th Congress of the CPSU it was noted that in the 11th five-year period a new large step was taken in raising the standard of living of the Soviet people and in development of all branches of the economy. National income increased by 17% and the increase in industrial production was 20%. This paper describes the plans for development of the power industry in 1986-1990 which envisage the provision of reliable power supply for the national economy based on more effective procedures, extensive introduction of new, progressive technology and on modernizing and re-equipping existing plants.

Troitskii, A.A. (USSR State Planning Committee, USSR). *Therm Eng* v 33 n 12 Dec 1986 p 645-648.

**084798 USSR POWER INDUSTRY.** Power generated in the USSR in 1986 reached 1599 milliard kWh, comprising 59 percent of the level in the USA. Power generated in the USSR exceeds the total produced in the developed capitalist countries of Europe. The paper describes some of the hydroelectric stations and nuclear power plants of the Soviet Union.

**084799 ESTONIAN SHALE-BASED POWER INDUSTRY-EXPERIENCE OF OPERATION AND THE PROSPECTS OF FUTURE DEVELOPMENT.** The experience of use of shales in the power industry based on the Estonian power system is of considerable importance for the power industry of the country as a whole, above all due to the fact that in the fairly near future in connection with the limited reserves of fossil fuel of high calorific value all the power stations of the country working on solid fossil fuel will have to change over to fuels of medium and low calorific value. The total installed capacity of the stations of the Estonian power system at the end of 1986 was 3311.3 MW, of which 3104 MW is generated by burning shale. The paper provides the performance characteristics of the Estonian power system working at base load and under conditions of load control in 1979-1986.

**084802 SECOND LAW EFFICIENCY AND COSTING ANALYSIS OF A COMBINED POWER AND DESALINATION PLANT.** Flow diagrams for exergy have been made for Unit 2 at the Umm Al Nar West power plant in Abu Dhabi. This unit is one of six in a combined power and desalination facility, each delivering 60 MW of electricity and 18000 metric tons per day of freshwater at design conditions. The diagrams show the rates of exergy flow between all of the components in the facility as well as the consumption in each. For the desalination facility, diagrams were developed for both summer and winter operation, at design conditions. The steam generation and power plant diagrams were made for full and three-quarter electrical loads, and full-load delivery of steam to the desalination plant. Furthermore, detailed exergy costing diagrams have been constructed for the steam/power facility, at both full and three-quarter electrical load conditions. Conclusions are drawn regarding means for improving the existing plant and future designs. (Author abstract). 14 Refs.

**084805 CREEP CRACK GROWTH BEHAVIOR IN POWER PLANT BOILER AND STEAM PIPE STEELS.** One of the important ingredients in remaining creep crack growth life assessment of elevated temperature power plant components is the material creep crack growth rate data. This report summarizes the currently available data on Cr-Mo and Cr-Mo-V steels most

commonly used in steam pipes and boilers. All data are correlated with the crack-tip parameter,  $C_t$ . The accompanying creep deformation data and tensile properties are also included. The influence of in-service degradation, test temperature and the welding parameters such as impurity level and post-weld heat treatment (PWHT) on the creep crack growth behavior were examined. It was shown that the influence of nominal material chemistry, service degradation and test temperature can be normalized into a single  $da/dt$  versus  $C_t$  trend for the base materials. It was also shown that the level of impurities and the PWHT can significantly influence the  $da/dt$  versus  $C_t$  behavior in weldments. (Author abstract) 22 refs.

**084806 HEAT ABSORPTION OF FURNACES WITH WATER LANCING BY DEEPLY-EXTENDING UNITS.** The main difficulty encountered in operating power stations working on low-cost solid fuels with a complex composition of the mineral matter is the intensive fouling of heating surfaces by ash and slag deposits. The results of this study are: 1. Cleaning the furnace waterwalls of steam boilers with water with the deeply-penetrating apparatus ensures a high thermal efficiency of the waterwalls when operating boilers both with dry and wet bottom ash removal. 2. The water lancing system enables a boiler to be operated for a virtually unlimited time with the same high thermal efficiency of the waterwalls. 3. Change in thermal efficiency of furnace waterwalls in the period between two cycles of cleaning takes place at a uniform rate. 7 Refs.

## Calculations

**084807 ENERGY CHARACTERISTICS OF ELECTROCHEMICAL POWER PLANTS WITH METHANE FEED AND HIGH-TEMPERATURE CELLS.** The paper describes a procedure for calculating the parameters of an electrochemical power plant (EPP) based on high-temperature cells. Methane serves as the raw fuel. The scheme involves a prior conversion of the methane with the water vapor and carbon dioxide which are the anodic reaction products of the high-temperature fuel cell (HTFC) with solid electrolyte. The mixture of hydrogen and carbon monoxide obtained as a result of the conversion is used as the reducing agent in the HTFC. The calculations show that the efficiency of such a power plant will be between 50 and 60%, depending on different parameters. (Edited author abstract) 5 refs.

## Computer Aided Design

**084808 SMART CAD BUILDS LARGE PLANTS.** The use of symbolic processing techniques in CAD systems is considered to be an effective way to automate design of large, complex products. It also promised to speed repetitive design tasks and reduce costs. It is shown how knowledge base, definition-driven systems dramatically speed power plant design. Using design definitions, constraints, and rules these systems determine the characteristics and attributes of parts as well as their relationship to assemblies. Object-oriented programming and symbolic processing techniques are used to compile these definitions into a knowledge base. Then, information is extracted from the knowledge base to create drawings, parts lists, bills of materials, process plans, and other documents. An example of definition-driven mechanical design systems from ICAD Inc., Cambridge, MA is introduced that reduced the design time of large, complex boiler parts for power plants by two-thirds, and lowered

operating expenses by making designers more efficient and have significantly reduced product lead times.

## Computer Applications

**084809 ARCHITECTURAL DEVELOPMENTS IN ON-LINE COMPUTER SYSTEMS FOR POWER STATIONS.** On-line computer systems for monitoring and controlling fossil-fuel and nuclear power stations were implemented in the 1970s. Developments in the technology of communications and chips have taken place in the 1980s, and two systems making use of such facilities are described, including current developments in prospect. These are monitoring systems for a fossil-fuelled station at Rihand in Uttar Pradesh, India, and for the new AGR at Torness in Scotland. Rihand is a coal-fired power station with two units each rated at 500 Mw (electric). Each unit has its own dual-redundant OLCs. Torness is an AGR station with two reactor/boiler/turbine units each rated at 660 Mw (electric). There is an OLCs for each unit in addition to auxiliary monitoring systems. 1 ref.

Humphries, Frank. *Power Eng J* v 2 n 2 Mar 1988 p 115-119.

## Computer Interfaces

**084810 POWER PLANT PRODUCTIVITY AND RELIABILITY INFORMATION SYSTEM.** An information system for handling equipment failure information of fossil fuel plants is described. This system produces 33 different reports, which contain failure statistics, plant availability, unavailability classified by cause, plant reliability indices, and maintenance productivity indices. Some of the innovations introduced by this system are: (1) event partition into any number of subevents for accurate description of event evolution, (2) separation of equipment and event cause for easy reporting, and (3) failure-mode information for better event description.

**Computer Simulation** See Also ELECTRIC POWER PLANTS—Geothermal Energy.

**084811 COMPACT, HIGH-FIDELITY SIMULATOR FOR POWER PLANTS.** Aging of existing plants, the high cost of constructing new ones, the need for cyclic operation, and pressures from regulatory agencies have forced the fossil-power industry to undertake plant-life extension and modernization programs. These programs require dynamic simulation codes to help engineers understand the behavior of plant equipment and processes and to predict the impact of proposed changes. In addition, plant operators need training simulators to help them become familiar with new equipment and to increase their expertise in areas such as plant heat rate. A description is given of the Compact Analyzer, which is an interactive program accessed through a PC, to help engineers devise and refine control strategies and make decisions on upgrading and cycling.

Khadem, Mostafa (Systems Control Inc, Palo Alto, CA, USA); Ipakchi, Ali. *Mech Eng* v 110 n 8 Aug 1988 p 58-61.

## Construction

**084812 CONCRETE POWER PLANT.** What may be one of the world's largest power plants with a superstructure essentially of reinforced concrete instead of conventional steel is now in operation in South Africa. The six boiler houses of the Lethabo coal-powered plant near Vereeniging, South Africa, were constructed of reinforced concrete to speed completion and reduce maintenance costs. Despite the tight construction schedule, the plant

was finished and in operation almost one year ahead of contractual commitments. This paper describes construction method and materials used.

## Cooling

**084813 EFFECT OF SUBCOOLING OF DISPERSED LIQUID ON CRITICAL HEAT FLUX WITH COOLING OF A PLANE SURFACE.** To ensure prescribed thermal state of elements of power plant extensive use is made of the method of cooling surfaces by dispersed liquid with different levels of subcooling. At the same time, information on critical heat fluxes with this means of cooling is very limited, and the applicability of relations derived for critical conditions with subcooled boiling of liquid in tubes and in channels is open to question. The paper describes a heat flux meter for determining parameters corresponding to critical heat transfer which was designed to carry out local measurements in the region of the space under the spray. The experiments showed that when a surface is cooled by a dispersed subcooled liquid, the critical heat flux density increases with the increase in subcooling and spraying density. 8 refs.

## Cooling Water

**084814 TIDAL MODEL TEST OF SALINE SEDIMENT-LADEN FLOW IN A TRENCH ON MUD FLAT.** An experimental method for the tidal model of a trench dredged on a mud flat to pump cooling water for a power station is proposed in this paper. Saline water at low concentration was used in the model, in which prototype sediment was employed as model sediment. The purpose of the model test is to estimate the silting rate of the tidal flow of saline sediment-laden water in the dredged trench before and after dykes have been built on both sides. Conditions for siltation similarity and erosion similarity are discussed. Under the conditions of lacking local siltation data for model verification, comparisons are made of the data on the silting rates of tidal flows in dredged trenches and analogous projects in nearby regions for the purpose of validation. (Edited author abstract) 10 refs.

**084816 INVESTIGATION OF THE p-v-T-DEPENDENCE OF THE  $\text{NaCl} + \text{Na}_2\text{SO}_4 + \text{H}_2\text{O}$  SYSTEM AT HIGH TEMPERATURES AND PRESSURES.** Design and development of present-day thermal power plants and chemical-technological processes are not possible without knowledge of the thermodynamic properties of working media and coolants. Aqueous solutions of salts are extensively used in the thermal power industry, the oil refining and chemical industries and many other branches of the national economy. This paper is devoted to an

experimental investigation of the p-v-T-dependence of aqueous solutions of NaCl + Na<sub>2</sub>SO<sub>4</sub> and is a continuation of the authors' previous work. A piezometric constant volume method<sup>2</sup> was used to determine the p-v-T-dependence of these systems within a wide range of change in parameters of state. This method enables experiments to be conducted in the liquid, two-phase, vapour and near-critical regions within a wide range of change in parameters of state. 6 refs.

**084817 WIRTSCHAFTLICHKEITSANALYSE DER REDUZIERUNG VON SCHADSTOFFEMISSIONEN EINES HEIZKRAFTWERKES.** [Economic Analysis of the Reduction of Emission of Pollutants from a Heating Power Plant]. The emission of pollutants from a heating power plant with 150 MW thermal output should be reduced by modifications to the most cost-effective extent possible. In this respect different variants in relation to cost and economics are compared. The special ratios for smaller plants for flue gas washing are discussed. From the flue gas desulfurization processes taken into consideration (spray absorption, wet washing with limestone suspension, the Wellman-Lord process, adsorption on active coal), the spray absorption process proved to be the most favorable. Primary measures should be sufficient for NO<sub>x</sub> reduction, but if necessary the SCR process can be used. Since electric power is also required at the same time by the heat consumer concerned, a check should also be made whether there would be economic advantages in combining district heat production and electricity generation. This proceeds from the limiting condition that on average as much electricity should be generated as is consumed. (Author abstract) In German. 30 refs.

**084818 ENERGIAINTUOTANNON PAASTOJEN MITTAAMINEN: HUIKASTEN SAHKOINEN LUOKITTELIJA JA SEN SOVELLUKSLIA.** [Measuring Energy Production Emissions: Electrostatic Particle Classifier and Its Applications]. The purpose of this study is to present a method of measuring the particle size distribution in the 0.01-1.0 µm diameter size range. The size distribution is measured by the Differential Mobility Particle Sizer (DMPS), in which the submicrometer particles are classified according to their electrical mobility. Electrical mobility is a function of the particle diameter and the number of elementary charges on the particle. The DMPS system uses a condensation nucleus counter (CNC) as the number concentration detector. A microcomputer performs the data inversion to obtain the particle concentration as a function of diameter. The volume (mass) distribution and the surface distribution are obtained by assuming spherical particles and a particle density of 1 g/cm<sup>3</sup>. In this study the size distributions of liquid DOP particles and solid NaCl particles were measured for particles generated by an atomizer. The electrostatic classification method provides a convenient source of monodisperse aerosol for instrument calibration. (Edited author abstract) In Finnish. 29 refs.

**Environmental Impact**

**084819 COMPENSATORY MECHANISMS IN FISH POPULATIONS: AN EPRI RESEARCH PLAN.** Using existing information, utility planners cannot accurately estimate the compensation by fish populations for power plant-induced mortalities. This plan maps a research effort to develop methods of quantifying this natural mitigation that would produce more-accurate assessments of utility impacts and help utilities make cost-effective decisions about power plant siting and design. The plan proposes two parallel, interactive research efforts - a key species program and a fellowship program - to develop a quantitative model for predicting the direction and magnitude of fish population response to site-specification impacts. Both are empirical programs: the first emphasizes the generation of data sets tailored to the needs of a modeling framework; the second tests and expands the concepts on which the models are based. As proposed, the research plan would last 9-11 years, with a funding requirement of approximately \$12 million.

**084824 ANALYSIS OF A WOOD-FUELED TRIM-BURNER SYSTEM FOR USE IN A COMBINED-CYCLE, WOOD-FIRED POWER PLANT.** This paper investigates the use of wood to fuel a trimburner incorporated in a combined-cycle, wood-fired power plant. The trimburner is designed to boost the temperature of the air stream entering the gas turbine. Wood conversion processes capable of producing a clean synthetic fuel were investigated since direct wood combustion products are too 'dirty' to be allowed to pass through the turbine blading. Of the three wood conversion processes considered (pyrolysis, gasification, methanol production), gasification was selected as the most applicable process for the trimburner concept. Three wood-fired trimburner systems employing an updraft gasifier design were developed and simulated. These subsystems differ in the way the producer gas, formed in the gasifier, was compressed to the trimburner operating pressure. (Edited author abstract) 8 refs.

**084825 GAS TURBINE-STEAM TURBINE COMBINED-CYCLE SYSTEMS.** A combined-cycle system consists of two or more cycles operating at different temperatures. Heat rejected by the higher temperature cycle is used to drive the lower temperature cycle to produce additional power and operate at a higher overall efficiency than either cycle by itself could achieve. Combined cycle plant is a promising mode of energy recovery and conservation and is an economically interesting proposition where inexpensive low-ash fuel is available for the gas turbine and consequently the majority of these plants will be located where natural gas is available for driving the gas turbine and also for supplementary heating in the waste-heat boiler. 6 refs.

**084827 HOW OPERATING CONDITIONS AFFECT PERFORMANCE OF HYBRID STEAM/GAS TURBINE PLANTS (PGU).** Design data and ratings for hybrid steam turbine and gas turbine plants (PGU) have been commonly cited in the scientific and technical literature, but actual PGU performance data arrived at empirically under on-stream conditions are often at sharp variance with the design data and ratings. Even in cases where steam parameters for hybrid steam/gas turbine plants (PGU) and steam-only plants (PSU) are identical, the heightened thermal performance of the former will make itself felt only when there is adequate and efficient gas turbine topping action over the steam portion of the cycle, i.e., when the efficiency of the initial uncombined gas turbine plant operating in an autonomous cycle is high. The advantages offered by PGU hybrids with a lowered air excess ratio in the off-gases improve as the required depth of load dump (in terms of percentage capacity) under operating conditions increases. 18 refs.

**084828 FRACTURING OF A PILOT PLANT FOR BOREHOLE HEAT STORAGE IN ROCK.** This paper describes research on a pilot plant in Lulea, Sweden. The plant consists of 19 boreholes, 52 mm in diameter, for heat supply and extraction; and 10 boreholes for temperature monitoring. All the boreholes are 21 m deep. The report describes in detail the performance and results of rock mass permeability and borehole permeability tests. It also discusses hydraulic fracturing and explosive fracturing in the boreholes. A simulation model of water flow in the test plant is described. The paper includes conclusions from the test results. (Edited author abstract) 18 refs.

**084830 OPERATIONAL PROCEDURES TO EVALUATE DECISIONS WITH MULTIPLE OBJECTIVES.** Many decisions facing utilities involve more than one objective, such as minimizing cost while maximizing environmental protection. In the work described here, actual electric utility applications illustrate operational techniques that can help utilities with multiobjective decision making. Presented in a workbook format, the report provides procedures and checklists for assigning values to potential outcomes of multiobjective decisions in a four-step process: In the first step, an analyst specifies distinct objectives. The second step requires associating attributes with each objective. For situations involving difficult-to-define attributes, such as minimizing environmental impact, the workbook discusses and demonstrates the construction of artificial scales and the use of proxy attributes. The third step requires quantifying relative values of the attributes. For the fourth step, an analyst uses the assigned values developed in the first three steps

to evaluate alternative scenarios.

**Monitoring**

**084831 MAXIMUM SALT CONTENT OF COOLANT AND CHOICE OF INTEGRAL MONITORING POINT WHEN STARTING SUPERCRITICAL POWER-GENERATING UNITS.** The blading of turbines of supercritical power-generating units is considerably more sensitive to deposits of salts and corrosion products than the steam-generating heating surfaces. A particularly important part of deposits, impairing operational reliability of turbines, is that of the corrosive compounds. Possessing fairly high solubility in the medium at supercritical pressure, these compounds pass through the circuit of a boiler at any of the concentrations in feedwater which are possible in practice, and then precipitate onto surfaces in the turbine flow section. In this work an analysis was made of practicability of standardizing characteristics and the practical advisability of standardizing. Measurements were made during the time of starting 300 MW supercritical generating units with TGMP-114 boilers and LMZ K-300-240 turbines at Syrdar' Central Power Station, where neutral/oxidant water treatment is practiced. 3 refs.

**Service Life**

**084836 ANALYSIS OF THE RESIDUAL LIFE OF HIGH-TEMPERATURE SYSTEMS.** Thermal power plants are high temperature systems. At high temperature under load, materials deteriorate continuously by diffusional processes like creep microstructural changes or oxidation. After a certain period, the residual life of a component can thus be defined as the time left till design life is reached. Simulation studies can help reach general conclusions about damage evaluation. For instance, that the simulation of service conditions by pure isothermal heat treatment does not give reliable results. For future simulation, the systematic integration of physical parameters, e.g., the cavity formation rate, particle coarsening or oxidation behavior in the extrapolation procedure should be considered. 30 refs.

**084837 LIFE-CYCLE COST COMPARISON OF ALTERNATIVE MATERIALS FOR FLUE GAS DESULFURIZATION COMPONENTS.** Life-cycle cost analyses of the use of stainless steels (SSs) and other corrosion-resistant alloys were compared with those of lined carbon steel in the construction of flue gas desulfurization components. The life-cycle cost analysis included all of the cost components that are affected by the materials of construction and was based on standard costing procedures followed by the utility industry. Although the capital costs for SS and corrosion-resistant alloys are generally higher than those of the lined carbon steel components, the life-cycle costs are less in most cases. Additional benefits include improved reliability and reduced downtime. Savings can be further increased by optimizing the selection of materials for individual components by matching the operating environment of the component and mechanical characteristics of the materials. Extensive field experience confirms the favorable conclusions of the study. (Author abstract) 3 refs.

## Structural Design

**084840** PROGRESSIVE CONSTRUCTION MATERIALS IN POWER MACHINE BUILDING. The continuous progress in power machine building is characterized by an increase in unit power of thermal, nuclear, and hydroelectric power plant units and imposes a number of requirements on the structural steels and alloys in use. The problems of using progressive structural steels and alloys, the development of new materials and the requirements on them for the power equipment developed in the period 1987-2000 were taken up at a meeting of the Scientific and Technical Council of the Ministry of Power Machinery in April 1987. In the reports and presentations of specialists from institutes, plants, special design offices, it was noted that structural steels and alloys used in the nuclear machine building in the production of steam boilers, steam and hydraulic turbines are at the levels of the better foreign materials for similar purposes in terms of calculated characteristics and technological properties, and satisfy the requirements imposed during design and manufacture of power equipment parts and components.

**084841** HOW TO SELECT ANTICORROSION LOW-FREEZING FLUIDS FOR HYDRAULIC TESTS ON POWER MACHINERY PRODUCTS. Plants manufacturing power equipment and power machinery have been furnishing outside packages ready for operation to high-rated conventional and nuclear electric power-generating stations in recent years. Techniques for

mechanical removal of water currently in use at power equipment plants (blowdown with compressed air, vacuum and non-vacuum flashing of water, gravity-aided draining) run into serious problems in terms of equipment requirements, power drain, and cost, and at that without guaranteeing complete removal of water present. A crucial deficiency of these techniques is lack of objective quality control of the water remaining within the system. The Physical Chemistry Institute of the USSR Academy of Sciences (IFKh AN SSSR) has recommended several nitrobenzoate amines combined with sodium and potassium bichromates, silicates, and phosphates as corrosion inhibitors for salt anti-freezes. The Institute of Inorganic Chemistry of the Academy of Sciences of the Latvian SSR has recommended complexes of boric acid with polyhydroxy carboxylic acids (concentrations to 1%) as inhibitor additives. 10 refs.

**084843** THEORY OF HEAT TRANSFER-IRREVERSIBLE POWER PLANTS. The observed degree of thermodynamic imperfection of existing power plants is explained based on a steady-state power plant model the irreversibility of which is due to three sources: the hot-end heat exchanger, the cold-end heat exchanger and the heat leaking through the plant to the ambient. While maximizing the instantaneous power output, it is shown that in addition to Curzon and Aihorn's optimum temperature ratio there exists also an optimum balance between the sizes of the hot- and cold-end heat exchangers. A graphic construction for pinpointing the optimum location of the power plant on the absolute temperature scale is presented. (Edited author abstract). 13 Refs.

**084847** OBTAINING OPTIMUM POWER OUTPUT FROM AN ENGINE TRANSMISSION UNIT WITH A TRANSMISSIVE TORQUE CONVERTER. It is generally recognized that the use of a torque converter (TC) in an engine transmission power unit (ETPU) improves the performance of the unit, and particular increases its ability to cope with sharp random changes in external loads. The authors cover the question of matching the TC with the engine and adjusting it to the external load, to form a unified power system, and obtain optimum potential power from the system. By optimum potential power is meant the maximum power which the unit can develop when operating in a given loading mode. Optimum matching of the engine and TC does not depend on the distribution of the random load, if the latter is expressed by a single-modulus curve. The power of the ETPU is practically independent of the form of the loading characteristic and the transmissiveness of the TC. 5 refs.

Raevskii, A.N. *Sov Eng Res* v 7 n 7 Jul 1987 p 22-25.

**084848** GRAPHIC MODELLING OF THE DYNAMIC PERFORMANCE OF MULTI-STAGE GEAR TRANSMISSIONS. For the mathematical modelling of dynamic processes, methods based on the use of equivalent circuits and graphs are available, permitting equations of motion to be derived automatically. The proposed method was used in writing a program for computer-aided calculation of dynamic loads in gear engagements and bearings of multi-stage transmissions with up to 20 elastic

links. The calculation is made for a system with distributed parameters, determined from the dimensions of sections of stepped shafts; these dimensions are entered when it is required to run the calculation. The program takes into account the stiffness and damping coefficients of the joints (key, spline, etc.) and the elastically connected masses and inertia moments. 6 refs.

**084849 ANALYSIS OF DYNAMICS BEHAVIOR FOR A POWER TRANSMISSION MECHANISM USING LINEAR GRAPH THEORY (IN THE CASE OF CONSIDERATION OF MOTOR, SUPPORT AND GEAR).** The importance of system design in the field of mechanical engineering has been increasingly recognized recently. But suitable and useful methods for machine design are not yet established. So we must derive easy and useful designing methods for each machine element. In the previous report, we derived a new designing method by linear graph theory and analyzed the results of the dynamic behavior of a power transmission mechanism as an example. In the report, we understand that the mechanisms which are subject to restrictions of high accuracy and high performance must be designed by considering the characteristic of each machine element. This report deals with a more general power transmission mechanism containing a motor, bearing, support and so on, and analyzes the results of dynamic behavior. Provided that the analytical model and system graph as in this report are prepared for the mechanism, the performance of the mechanism is easily grasped by this method. (Author abstract) In Japanese. 6 refs.

**084850 REVERSING SYSTEM FOR GAS TURBINES AND HIGH-SPEED ENGINES.** A particularly interesting transmission system is being installed in a large and fast fleet replenishment ship now under construction for the US Navy by NASSCO (National Steel and Shipbuilding Co) of San Diego. Two General Electric LM2500 gas turbines will be driven through Cincinnati double-reduction locked-train combining and reduction gears, incorporating SSS-Tosi reversing systems. The gear arrangement will be conventional, with each gas turbine input pinion driving two parallel secondary shafts, and all four secondary pinions engaging with the main gearwheel. An auxiliary gearbox fitted to the far end of each turbine drive train contains the reversing mechanism components. A second subject concerns how, with the adoption of a torsional elastic damper, severe vibration problems with a large slow-speed engine were successfully solved.

Anon. *Mar Eng Rev* Jun 1988 p 25-27.

**084851 LINEAR-MOTION ADVANCES: PATHWAYS TO GLORY.** The development of linear motion devices is surveyed. Most linear motion devices can be teamed with like or unlike devices into systems of two or more axes of linear motion. Linear actuation devices for single-axis motion include: various complex linkages such as walking beams or rod-and-crank mechanisms; cam drives with fixed-axis followers; gear rack and pinion sets; transmission chain drives in the linear part of chain travel, with or without special attachments; belt drives in the linear part of belt travel, with or without special attachments; plastic drive tapes; sliding-action leadscrews, with nuts; ball-bearing leadscrews, with nuts (ballscrews); skewed rollers on a rotating cylindrical rod (threadless rod; traction motion); fluid-power cylinders, with direct-driving rod, rodless cylinders, and cable cylinders; electric solenoids; electric linear motors. Some linear motion systems are reversible and capable of back-driving.

**084857 CALCULATION OF THE CRITICAL SPEEDS OF A DRIVE WITH HARMONIC GEAR TRANSMISSION.** When investigating the dynamic stability of drives incorporating harmonic gear transmissions (HGT), we have to take into account the transverse vibrations of HGT elements. Determination of the natural frequencies of these vibrations is of the greatest interest, its purpose being to eliminate resonance phenomena where the kinematic error and non-uniformity of rotation reaches their maximum values. 6 refs.

Popov, P.K. *Sov Eng Res* v 7 n 3 Mar 1987 p 17-18.

**084858 CONTINUOUSLY-VARIABLE TRANSAXLE FOR FRONT WHEEL DRIVE VEHICLES.** A major problem has been in transmitting the power from the engine to the driving axles. Many attempts have been made to simplify manual gear changing and to eliminate it, as witnessed by the progression through synchromesh and epicyclic gearboxes to automatic drives operating electrically or hydraulically. One of the major problems has been the loss of power through the transmission, with consequent lack of economy on fuel. This article describes a continuously-variable transaxle designed specially for smaller front-wheel-drive vehicles on which the fuel consumption is approximately the same as for manual gearboxes, with the advantage of smooth gear changing comparable to a gearbox with no less than six speeds. (Edited author abstract)

Anon (Ford Motor Co). *Power Int* v 33 n 389 1987 p 174-176.

**084859 IDEAL CHARACTERISTICS OF A VARIABLE RATIO BELT DRIVE.** A fundamental theory concerning the theoretical power-torque envelopes over the speed ratio range of a general variable ratio belt drive is presented, to the best of the author's knowledge, for the first time. This theory applies to both V and flat belt drives, and is independent of the detailed designs. The analysis is based on two limiting factors, namely the maximum tension and the tendency of the belt to slip bodily on one or both pulleys assuming that the centre distance and the belt length are constant. These above factors determine the power and torque envelopes. The most suitable envelopes for the design purpose of the variable ratio belt drive are those of compact size, maximum belt tension and relatively high transmitted power. (Author abstract)

## Electronic Properties

**084862 SELF-CONSISTENT BAND STRUCTURE OF PRASEODYMIUM UNDER PRESSURE.** Praseodymium (Pr) like cerium (Ce) has a number of phase transitions under pressure. In this work, we present a fully self-consistent band structure of Pr at four different pressures, using the linearized augmented plane wave method. For this purpose a potential of the muffin-tin form has been assumed. The exchange and correlation parts of the potential have been calculated by the local density formalism. The results show that between Pr III and Pr IV a band broadening occurs that looks similar to the band broadening between the  $\gamma$  and  $\alpha$  phases of Ce, in the sense of similar f-band widths. From the band-structure results, the density of states, coefficient of linear specific heat and superconducting transition temperature are calculated and are compared with experimental data wherever possible. (Author abstract) 32 refs.

## Purification

**084863 ALTERATION OF SOME PROPERTIES OF PRASEODYMIUM METAL BY ELECTRON BEAM MELTING.** A commercial Pr rod with a purity of 3N(REO) was melted in an electron beam furnace under a pressure of  $10^{-5}$  approx.  $10^{-6}$  mmHg. The content of hydrogen decreased from 76 ppm to 4 ppm and the Vickers hardness number dropped from 58 to 32. The melted metal showed a higher oxidation resistivity, while the starting rod was easily cracked and oxidized. (Author abstract) 4 refs.

## Radiation Effects

**084864 STRUCTURAL TRANSFORMATION AND CHEMICAL REDUCTION OF  $\text{Pr}_2\text{O}_3$  INDUCED BY THE ELECTRON BEAM DURING MICROSCOPICAL EXAMINATION.** The effects of electron beam irradiation on  $\text{Pr}_2\text{O}_3$  were followed at high

resolution in a JEM-4000EX electron microscope. Two categories of electron beam effects are reported. In one image sequence, the orientational transformation of  $\text{Pr}_2\text{O}_3$  from the [100] to the [313] direction was observed to occur. In another sequence, reduction of  $\text{Pr}_2\text{O}_3$  to  $\text{Pr}_2\text{O}_2$  resulted from intense beam irradiation. Electron diffraction patterns showed the further reduction of the specimen to  $\text{Pr}_2\text{O}_2$  and finally to  $\text{Pr}_2\text{O}_3$ . (Author abstract) 11 refs.

## PRASEODYMIUM ANTIMONY ALLOYS

### Phase Diagrams

**084869 PHASE DIAGRAM OF THE Pr-Sb SYSTEM.** This study contains a phase diagram of the Pr-Sb system which was built up using high temperature differential, x-ray phase and microstructural analyses. Praseodymium, containing 99.84% of the basic metal, and antimony of superhigh purity were used for the investigation. The preliminary synthesis of the alloys was carried out in evacuated (up to  $10^{-4}$  mmHg) molybdenum ampoules at 500°C. The X-ray phase analysis was performed on powders using a Tu-62M diffractometer and a HZG-3 goniometer with Cu K radiation. The microstructural analysis was carried out with an MIM-8 microscope. The phase with the highest melting point is the praseodymium monoantimonide which melts congruently at 2170°C. At 1950°C it undergoes a reversible polymorphic transformation. Microstructural analysis revealed that the samples close to equiatomic composition always contain a second phase. 11 Refs.

## PRASEODYMIUM IRON BORON ALLOYS

### Amorphous

**084870 MAGNETIC PROPERTIES OF MELT-SPUN (Pr, Dy)-(Fe, Co)-B SYSTEM ALLOYS AND THEIR BONDED MAGNETS.** In melt-spun ribbon of (Pr,Dy)-(Fe,Co)-B alloys prepared by the single roller method, the effects of composition and substrate surface velocity on the magnetic properties were studied. Bonded magnets were made of  $\text{Pr}_{15}\text{Fe}_{77}\text{B}_8$ ,  $\text{Pr}_{15}(\text{Fe}_{0.9}\text{Co}_{0.1})_{77}\text{B}_8$ , and  $(\text{Pr}_{0.95}\text{Dy}_{0.05})_{15}(\text{Fe}_{0.9}\text{Co}_{0.1})_{77}$ . Values of a maximum energy product in  $\text{Pr}_{15}\text{Fe}_{77}\text{B}_8$ ,  $\text{Pr}_{15}(\text{Fe}_{0.9}\text{Co}_{0.1})_{77}\text{B}_8$  and  $(\text{Pr}_{0.95}\text{Dy}_{0.05})_{15}(\text{Fe}_{0.9}\text{Co}_{0.1})_{77}$  prepared at a substrate surface velocity of 11.8 m/s were 98.3 kJ/m<sup>3</sup>, 97.4 kJ/m<sup>3</sup> and 97.8 kJ/m<sup>3</sup> respectively. The best magnetic property obtained was  $(\text{BH})_{\text{max}} = 64.8 \text{ kJ/m}^3$  in  $\text{Pr}_{15}\text{Fe}_{77}\text{B}_8$ . The temperature coefficients of  $B_r$  and  $H_{CB}$  were improved by Co substitution for Fe and Dy for Pr. (Edited author abstract). 12 Refs. In Japanese.

### Structure

**084871 STUDY OF THE ONE-DIMENSIONAL COMPOSITION-INCOMMENSURATE STRUCTURE OF  $\text{Pr}_{1+x}\text{Fe}_4\text{B}_4$ .** The crystal structure of the B-rich phase  $\text{Pr}_{1+x}\text{Fe}_4\text{B}_4$  was studied by means of X-ray powder diffraction and electron diffraction methods. One-dimensional composition-incommensurate structure along the c-direction is found. The structure is composed of Fe-B substructure and Pr substructure. Both substructures have tetragonal symmetry with the same lattice parameter a, but there is no lowest common multiple relation between  $c_{\text{Fe-B}}$  and  $c_{\text{Pr}}$  parameters. The lattice parameter at room temperature of  $\text{Pr}_{1+x}\text{Fe}_4\text{B}_4$  is a = 0.7144,  $c_{\text{Fe-B}} = 0.3900$ ,  $c_{\text{Pr}} = 0.3485$  nm and after quenched from 950°C a = 0.7138 nm,  $c_{\text{Fe-B}} = 0.3881$  nm and  $c_{\text{Pr}} = 0.3618$  nm. The space groups of substructures of Fe-B and Pr are  $\text{P4}_2/\text{ncm}$  and  $\text{I4}/\text{mmm}$ , respectively. (Edited author abstract). 5 Refs.

## PRASEODYMIUM IRON COBALT CHROMIUM ALLOYS

## Magnetic Properties

**084872 MAGNETIC PROPERTIES OF  $\text{Pr}_2\text{Fe}_{14-x}\text{Co}_x\text{Cr}_y\text{B}$  COMPOUNDS.** The replacement of iron by cobalt leads to an increase in Curie temperatures but decreases the anisotropy field. Studies of  $\text{Nd}_2\text{Fe}_{14-x}\text{Cr}_x\text{B}$  compounds have shown that replacement of Fe by Cr results in an increase of the uniaxial anisotropy for  $0 \leq x \leq 1$ . The present note represents an extension to corresponding compounds with praseodymium. Magnetic measurements were performed at 77 to 800 K in fields up to 26 KOe. The values of the saturation moment,  $M_S$ , were obtained from Honda ( $M$  versus  $1/H$ ) plots. 12 refs.

**084874 KINEMATIC COUPLINGS FOR PRECISION FIXTURING - PART I: FORMULATION OF DESIGN PARAMETERS.** A closed form analysis for the design of a three-groove kinematic coupling is developed and used to design a 356 mm (14 in) diameter kinematic coupling with 28.6mm (1.1/8 in) diameter balls and 45 kN (10,000 lbf) preload. When the coupling is subjected to cutting loads in the order of 75 N (17 lbf), the resulting wall thickness errors in a 254 mm (10 in) diameter hemispherical part are: (1) a  $0.36\mu\text{m}$  ( $14\mu\text{in}$ ) error from the cutting force, and (2) a  $0.89\mu\text{m}$  ( $35\mu\text{in}$ ) error with a 2% preload error. If ceramic balls and grooves are used, fretting corrosion of the coupling interface can be avoided and the coupling can operate in a corrosive environment. The kinematic design is unaffected by film contamination and does not require an extensive wear-in period. Preliminary experiments show the coupling to be repeatable to  $\pm 0.25\mu\text{m}$  ( $\pm 10\mu\text{in}$ ). (Author abstract) 8 refs.

## Technology Transfer

**084877 ENGINEERING TO NANOMETRE ACCURACIES.** Nanotechnology is the technology associated with the manufacture and measurement of components to accuracies between 1 nm and  $1\mu\text{m}$  ( $10^{-9}$  to  $10^{-6}$  m). To those who work in the electronics industry where individual structures on a semiconductor chip are fabricated to nanometre tolerances, nanotechnology has been familiar for years but for many others the concept of mechanical engineering to these levels of precision is unheard of and unnecessary. However, the ability to mechanically engineer to nanometre precision has already created, in just a few years, world markets of many billions of pounds in products with which all of us are familiar.

**Applications** See PAPERMAKING—Drying.

**Automation** See Also GLASS MANUFACTURE—Pressing.

**084880 AUTOMATING THE POWDER COMPACTING PRESS.** Cincinnati Inc. of Cincinnati, Ohio, has introduced a PM part manipulator, designated Model 523, which can be fitted to any of its powder presses up to 220 tons, and which incorporates a weighing station for

quality control or statistical process control. Cincinnati has also introduced a 'fast set up' module for these presses which allows for greatly improved productivity and flexibility. The '523 Parts Manipulator' is an electromechanical transfer unit. It is capable of picking a part off the die, transferring it to a scale, weighing the part and then transferring the part to a handling station. This parts manipulator can be mounted on any 66, 110 or 220 ton Cincinnati compacting press that is microprocessor controlled and has a motorised feeder. The manipulator is a two axis microprocessor controlled, programmable system. There are two axes: the vertical motion of the Y-axis and the horizontal motion of the X-axis. Both axes are electrical servo controlled and independently programmed by the operator.

Anon. *Met Powder Rep* v 42 n 9 Sep 1987 p 642-644.

## Computer Aided Analysis

**084881 COMPUTER AIDED ANALYSIS OF SCREW PRESS DYNAMICS.** Dynamic mechanical and mathematical models for screw press and plastic-working processes of die forging and coining were developed, verified with experimental observations and used for analysis of screw press dynamics. Some results helped to optimize nut design elements of a screw-working mechanism. (Edited author abstract) 19 refs.

## Control

**084882 COMPACT PRESS CONTROLLER FOR SHEET METALWORKING.** The necessity to improve the economics of sheet metalworking has also spread to power presses, bringing with it greater automatic control and greater stroke rates. Nowadays, presses capable of producing 2000 items per minute are no longer a rarity. Implementation details are reported. (Edited author abstract)

Fehr, Manfred (Siemens AG, Geraetewerk Erlangen, West Ger); Mosburger, Jakob; Rissmann, Gerhard. *Energy Autom* v 9 n 2 Mar-Apr 1987 p 24-27.

**084883 COMPACT AND MODULAR CONTROLS FOR PRESSES.** Rapid set-up for new parts and operator prompting in the event of faults have been provided as standard and at an acceptable cost for a number of years in press lines and progressive presses. This user-friendliness is now also available in singly operated, small and medium-sized presses in the form of the WS510P compact control. (Author abstract)

Klose, Guenter (Siemens AG, Nuremberg, West Ger). *Energy Autom* v 9 Oct 1987 p 62-65.

**084884 FLEXIBEL GESTEUERTE STANZSTRABEN FUR TEILEFAMILIEN.** [Flexibly Controlled Stamping Lines for Component Families]. Decreasing batch sizes and growing type variety in sheet metal working generally results in the requirement for more flexibility in set-up changing for given component families. The consequence of this in turn is a demand for stamping lines permitting programmed set-up changing either within strip profiling and forming facilities or in press lines made up of conventional presses. This is a report on this trend with an example from refrigerator production. (Author abstract). In German.

Salinas, Ramirez, Felix. *Werkstatt Betr* v 121 n 6 Jun 1988 p 517-521.

**084885 INTERNATIONAL PUNCHING.** A joint venture between Bruderer of Switzerland and Siemens of West Germany has resulted in a flexible punching cell. The aims of the project were to combine a material storage, tool storage and punching into one machine simplifying the transport of coil and dies and reducing set up times from 40 minutes plus to 4 minutes. The crucial feature of

the cell is, of course, its performance, governed by the Siemens control system, which consists of a Simatic central controller with 20Mb of data storage, including all material and tool, storage data, and four satellite controllers for different parts of the process.

Anon. *Prod Eng (London)* v 67 n 9 Oct 1988 p 34.

## Control Systems

**084886 SAFETY START SWITCH FOR PRESS CONTROL.** The safety starting device for press control is recommended for use at enterprises which produce and use forging and press machinery with two-handed control. The proposed device prevents accidental actuation of the press, as well as the possibility of operating with one button when the contacts of the other button are closed, thus improving the reliability and safety of press operation. Since the introduction of the safety starting device at the Dimitrovgrad Automotive Component Plant, no accidental press actuations have occurred.

Fomakin, A.N. *Sov Forg Sheet Met Stamping Technol* n 2 1987 p 110-111.

## Corrosion Resistance

**084887 PROPERTIES AND MANUFACTURE OF THE CORROSION-RESISTING PLATE AND FRAME PRESS.** The acid/alkali resistance and manufacture of the corrosion-resisting plate and frame press made of rubber and poly-propylene are discussed. The structures and characteristics of various types of plate and frame often used are contrasted. The failures which often happen in production are analysed and preventing methods are presented. (Author abstract) 9 refs. In Chinese.

**Design** See Also POWDER METAL PRODUCTS—Manufacture; POWDER METALLURGY—Compaction.

**084888 DIMENSIONING OF AN EXTRUSION PRESS.** In connection with investigations on a so called ram or piston feed lock for introducing solids into, or discharging solids from, pressurized spaces, which operates on exactly the same principle as an extrusion press, the question as to the relationship between the piston pressure to be applied and the length to be adopted for the die channel has to be considered. The criterion is that a particular compaction pressure must not be exceeded. A consistent distinction is drawn between the compaction phase and the extrusion (or conveying) phase. On the basis of theoretical considerations relating to bulk materials and correspondingly different formulations for the pressure conditions established, it is possible to obtain a differential equation whose solution yields an unambiguous relationship between compaction pressure and required channel length. A dimensionless representation of the results based on this approach offers a simple method of determining the dimensions of extrusion presses taking due account of the compaction phase and the extrusion phase. (Edited author abstract). 16 Refs.

**Energy Utilization** See STEEL SHEET—Forming.

## Feeding

**084889 MECHANIZED SYSTEM FOR STRIP FEEDING IN PRESSES.** A system has been developed for handling the strips left over after cutting large sheets in the main production shops. These strips are fed to the press section which produces consumer goods. The system consists of receiving and discharging tables, a modernized roll-feed device (type VP35A), two guide rollers, and thrust units. The system is connected to the KD-2330 press. The incoming strip is placed on the receiving table and inserted between the push rolls of the feed device. The guide rollers are intended for locating the straight edge of the strip, preventing transverse movement, and guiding

the strip onto the top surface of the die. The flat spring of the thrust unit keeps the strip pressed against the faces of the guide rollers. At the exit of the die zone the strip is engaged by the pull rolls of the feed device and is removed from the press. The used strip falls on the discharging table and is thrown in a waste container.

## Performance

**084894 DYNAMIC ACCURACY OF MECHANICAL PRESS - MEASUREMENT OF DYNAMIC CHARACTERISTICS BY A SIMULTANEOUS MULTI-MEASURING DEVICE.** In order to investigate

the dynamic characteristics of mechanical presses, precise measurement of dynamic accuracy is attempted by a simultaneous multi-measuring device. This device has one load cell, and six noncontact sensors used to detect the slide displacement in x, y and z directions relative to the bolster. The blanking operation is carried out by using a straight-side press. Steel plates (SPCC, 1 mm in thickness) are blanked varying the stroke number per minute. The results obtained are as follows: (1) Immediately after break-through, the vibration of the lower surface of slide relative to bolster becomes larger, and the inclination between the slide and the bolster is also bigger than that before break-through. (2) As the stroke number per minute increases, a) the position of lower dead point of the slide becomes lower, b) the vibration of slide inclination becomes larger even before break-through, c) the lower surface of the slide is given a violent distortion and the maximum amplitude of inclination increases immediately after break-through. (Edited author abstract) In Japanese. 8 refs.

**Processing** See VENEER—Drying.

## Productivity

**084895 FEEDING HUNGRY PRESSES.** Just-in-time demands have wrought big changes for the stamping industry. Short runs, fast change-overs, and tremendous cost-squeezing competitive pressures have forced a lot of reluctant stampers to take a bold leap into the brave new world of automated press feeding to get the productivity they need to compete. Although few can afford the investment in large press lines recently made by General Motors and other large automotive companies, advances in transfer automation are helping a lot of stampers retrofit existing presses with automated transfer equipment and get significant productivity increases. The effects are already measurable. A recent study of Michigan's stamping industry revealed autobody production rates two to three times faster than were typical just a few years ago, uptimes have nearly doubled from 40 to 50 percent to 70 and 80 percent, and rejection rates dropped from 3 to 5 percent to fractions of a percent.

**084897 EFFECTS OF AEROSOL SCATTERING ON REMOTE PRESSURE MEASUREMENT VIA OXYGEN A-BAND ABSORPTION.** The technique recently proposed by I.J. Barton and J.C. Scott to monitor surface pressure using absorption of reflected sunlight in the oxygen A-band is subject to errors due to aerosol scattering. Errors arising from specified uncertainties in the aerosol optical depth are evaluated. Zones of feasibility are presented for typical surface conditions and aerosol parameters. This shows that the region within which an accuracy of 2 mbar is obtained is so small as to render the technique operationally unviable, even if monitoring of the aerosol optical depth to  $\pm 0.02$  was available. (Edited author abstract) 13 refs.

**084898 MEASURING PROCESS PRESSURE - A USERS GUIDE.** The object of this paper is to consider aspects of pressure measurement as applied to process plant from the point of view of a typical user. An extremely basic approach will be made to the subject and some initial consideration of the fundamental measuring principles of pressure sensors will be discussed. Criteria that should be considered when selecting a sensor will be outlined and a simplified set of pre-selection guidelines will be proposed. It is not the objective of this paper to discuss specific applications in any detail, as these would be too diverse and numerous, although pressure sensing will be considered in general.

Challoner, Tony (Warren Spring Lab, Stevenage, Engl). *Meas Control* v 20 n 8 Oct 1987 p 19-23.

**084899 INTERMEDIATE RANGE PRESSURE MEASUREMENT.** This article deals with a variety of techniques and applications in the measurement of the intermediate range of pressures centered about atmospheric pressure, with emphasis on the use of silicon sensor technology and high accuracy systems, using the vibrating cylinder transducer. The extension of the use of the silicon sensor is described through a series of application areas leading to their use in precision pressure calibration instruments. The use of the vibrating cylinder

transducer in these instruments to meet the highest accuracy requirements is also described. 1 ref.

**084900 MEASURING THE PRESSURE IN A GAS THERMOMETER.** The All-Union Technical Physics and Electronics Research Institute has completed research on a precision gas thermometer for this range and has derived new numerical values for the thermodynamic temperatures of the main reference points on IPTS-68 and correspondingly the deviations from the thermodynamic scale. This constant-density gas thermometer uses a system without a harmful volume. The main readout instrument is an interference manometer especially built for the purpose. The manometer design features have been described. Here the authors consider the error sources in pressure measurement, together with the corrections made and the performance of the instrument as a whole. 17 refs.

**084901 FLOW EFFECTS ON DYNAMIC PRESSURE MEASUREMENTS.** The measurement of dynamic pressure signals in wind tunnels is often required when it is impractical to locate a pressure transducer at the source. In this case, signals may be transmitted to a transducer through tubing that serves as a transmission line. The dynamic characteristics of fluid transmission lines used to transmit these dynamic pressure signals need to be known if accurate measurements are to be obtained. The response of transmission lines and the effects of flow in the line and across the line inlet are described. (Author abstract) 26 refs.

**084902 PRESSURE MEASUREMENT IN HAZARDOUS AREAS.** Initially developed for use in aerospace and defence applications, the sputtered thin film strain gauge sensor has exhibited excellent performance, particularly in terms of long term stability. Maintenance-free operation over extended periods without the need for periodic recalibration is one of the consequences. Features of the basic sensor are described together with some of the changes which have been introduced in order to provide the desired safety features.

Clare, P.M. (Transamerica Instruments, Basingstoke, Engl). *Meas Control* v 20 n 9 Nov 1987 p 45-48.

**084903 ADVANCED DESIGN CONCEPTS FOR FUSED QUARTZ PRESSURE TRANSDUCERS.** The author discusses the engineering design considerations applied in the development of a laboratory grade pressure standard utilising a fused quartz Bourdon tube transducer. Its adaptation to uses in field services and process control industries is described. The applications for generating accurate pressures are of equal importance than just measuring pressure accurately. The sensor has the ingredients needed for a pressure controller when a servovalve is added to the system.

Worden, Ray D. (Ruska Instrument Corp, Houston, TX, USA). *Meas Control* v 20 n 9 Nov 1987 p 51-55.

**084904 GENERATION OF STABLE HYDRAULIC PRESSURES IN CALIBRATION SYSTEMS.** The availability and use of higher accuracy pressure standards and more sensitive pressure transducers means that special consideration must be given to the calibration systems. In addition to ensuring that the environmental conditions under which such equipment is used are appropriate, care must be taken in the selection of a suitable pressure regulation and control system. Using motorised means for pressure generation reduces operator fatigue and gives more reliable and repeatable results compared to manual systems.

**084906 KAPAZITIVS DIGITALDRUCKMEßGERÄT UND SEINE ANWENDUNG. [Capacitive Digital Pressure Gage and Its Application].** A digital pressure gauge working according to a capacitive principle and having ranges from 0 to  $\pm 99.9$  Pa and 0 to  $\pm 999$  Pa has been developed and tested. Its maximum error is in the order of magnitude of 1 percent. Owing to its very good dynamic properties the unit may be used for measuring both static and dynamic pressures up to a limit frequency of 25 Hz. Efforts are continued to optimize the pressure pickup in the interest of improving its temperature error, long-time stability and limit frequency. (Author abstract) 5 refs. In German.

**084907 PRESSURE MEASUREMENT IMPROVES, BUT CALIBRATION IS STILL NEEDED.** There have not been many new methods for measuring pressure introduced in the recent past, at least not as many as there have been for other process variables like flow and temperature, but the advances in electronic manufacturing technologies and the addition of communications capabilities have had an effect on pressure sensors and transmitters. New materials, improvements in manufacturing, and advancing electronic technologies are providing both low cost and high cost types of pressure measurement.

Blickley, George J. (Control Engineering, USA). *Control Eng* v 35 n 5 May 1988 p 87-89.

**084908 CHARACTERIZATION OF CONTROLLED CLEARANCE PISTON GAUGE USING DIFFERENT WORKING FLUIDS UP TO 5 MPa.** A systematic study carried out to characterize the controlled clearance piston gauge in the pneumatic pressure region up to 5.09 MPa full-scale pressure using different working fluids such as argon, nitrogen, helium and hydrogen is described. The characterization was conducted/carried out by measuring the fall rate of the piston as a function of the jacket pressure ( $P_j$ ) in order to determine the stall jacket pressure ( $P_{zj}$ ) corresponding to the zero clearance between the piston and cylinder. A comparatively greater reproducibility in the  $P_{zj}$  value is obtained for helium and hydrogen as compared to that of argon and nitrogen. The effects of the temperature of the operation on the fall rate in this piston gauge using gaseous nitrogen as the working fluid are also reported. (Edited author abstract). 12 Refs.

## Automation

**084910 DEVELOPMENT OF SENSING SYSTEM OF PIEZOELECTRIC CERAMICS MEASURING CONTACT PRESSURE DISTRIBUTIONS.** In this paper, an automatic sensing system measuring contact pressure distributions is proposed. The sensing material is made of piezoelectric ceramics. To measure electric charge in the material produced by contact pressures, a special electric circuit is designed by using a peak hold circuit. A micro computer (NEC PC-9801) and a multiplexer controller are used to automatically measure the contact pressure distributions. By using the ceramic sensor for  $5 \times 5$  measuring points, the pressure distributions for several contact problems are measured. The obtained total forces and the pressure distributions are compared with the corresponding acting forces and the theoretical values. From the results, it is recognized that the proposed sensing system is excellent in reliability and durability. (Author abstract) 10 refs. In Japanese.

**084912 PRESSURE SENSORS: THE ADVANTAGES OF GOING DIGITAL.** There are several analog devices that convert process pressure into an electrical signal. Traditionally, each device has been selected for application in a particular instrument because of its performance characteristics, physical attributes, and cost. This article deals with the advantages of using frequency-based pressure sensors and digital counting circuits for pressure measurement. It covers digital sensors as they are applied in a range of pressure-based measurements such as flow, differential pressure, hydrostatic tank gaging, and applications requiring direct pressure readings.

**084913 INSTRUMENT FOR MEASURING PRESSURE IN SOLIDS-LADEN FLOWS.** The efficiency, reliability and safe operation of boiler plants depend to a great extent on the accuracy and reliability of monitoring pressure of solids-laden gas flows, for example air/pulverised coal flows, air which has been regeneratively preheated, drying agent, flue gases, etc. The Pitot or Stanton tubes used for this purpose are insufficiently reliable and precise due to obstruction by solids of the pressure receivers and impulse lines. This article considers an instrument of improved reliability in measuring static pressure of solids-laden gas flows. It can be used also for measuring pressure drops, in Venturi tubes. 3 refs.

**084914 MODELING RATE EFFECTS AND CYCLIC LOADS WITH THE PRESSUREMETER.** A

relatively new tool, the cone pressuremeter (CPMT), was used in order to evaluate its usefulness in predicting the effects on solids due to various rates of loading and to repetitive loading. Field tests were conducted in two phases. The first phase included 24 CPMT tests, at the Texas A&M University research annex, which were designed to show 1) if the CPMT could be used to predict the effects on the soil due to both rate effects and repetitive loads; and 2) if the CPMT should be inserted into a prebored hole to the desired test depth or if the CPMT should be driven to the desired test depth. The soils at the research annex were a clay and a sand. It was concluded that a single CPMT test could be used to model both rate effects and cyclic effects on the soil modulus and that the most consistent method of inserting the probe was to place it in a prebored hole. It was also concluded that a linear relationship exists between the exponents  $n$  in both modeling equations and the normalized CPMT stress level. (Edited author abstract). 10 Refs.

**084915 DEVELOPMENT OF A HIGH PRESSURE SECONDARY GAUGE USING AUCR SPIN-GLASS SYSTEM.** The metrological behavior of an Au + 6.4 at%-Cr pressure gauge under the influence of external parameters, at standard range of temperatures and for pressures up to 600 MPa is explained. This is based on pressure and temperature effects on indirect RKKY and direct d-d exchange interactions between the spins associated with magnetic Cr impurities in spin-glass alloys such as AuCr. Special attention is paid to interpretation of the positive resistance-pressure coefficient, also known as an 'abnormal' effect. Other metrological properties (i.e., perfect linearity, lack of hysteresis, and temperature stability under low and high pressure) of pressure gauges made from AuCr spin-glass alloy are discussed. Suggestions for future improvements are included, along with measurements of low temperature (77 K) effects in AuCr pressure gauges. An approach to understanding these effects in terms of magnetic properties of the alloy is presented. 9 refs.

**Sensors** See Also OPTICAL FIBERS—Sensors.

**084917 SIMPLE MULTIMODE FIBRE INTERFEROMETRIC SENSOR FOR PRESSURE-RELATED MEASUREMENTS.** A multimode optical fiber sensor is described, based on phase change information due to interference between light reflected from the fiber end and from a flexible membrane. The experimental version made is tested to be used for gas and liquid pressure measurements in medical and industrial applications. The mode of operation is described in terms of the combined effects of the mode transformations in the passive fiber components and at the reflections. It is shown that the uniform mode transformation properties, as found in the splitters and couplers made in the

Fused-Head-End method, are indispensable. Applying the Fused-Head-End directly, without a single fiber connected, the device can operate simultaneously as an intensity-based proximity sensor. (Author abstract). 14 Refs.

**Standards** See Also VACUUM TECHNOLOGY—Gases; VACUUM TECHNOLOGY—Measurements; VACUUM TECHNOLOGY—Standards.

**084918 STANDARDS FOR THE MEASUREMENT OF PRESSURE.** This paper will concentrate on standards for the measurement of static 'absolute' pressures (referred to absolute vacuum), static 'gauge' pressures (referred to ambient pressure) and static differential pressures (superimposed on a defined bias or line pressure). The problem of measuring dynamic pressures is one of growing importance but it is unfortunately very difficult to provide a comprehensive set of dynamic measurement standards because of the wide range of amplitudes, frequencies, waveforms and static bias pressures occurring in practice. 21 refs.

Stuart, P.R. (NPL, Teddington, Engl). *Meas Control* v 20 n 8 Oct 1987 p 7-11.

**084919 METHOD OF CONSTRUCTING SECONDARY STANDARDS FOR ABSOLUTE PRESSURE ON THE BASIS OF FIXED POINTS FOR PHASE TRANSITIONS IN PURE SUBSTANCES.** Mercury and piston standards give the highest accuracy in measuring absolute pressures, but the equipment is complicated and not capable of being transported, so it is impossible to compare stationary standards directly, and thus to evaluate the unification in absolute-pressure measurement. Interest attaches to devices based on the triple point or a continuous part of the first-order transition curve for a pure gas to provide simple and transportable secondary standards giving the necessary stability and reproducibility on comparison with the initial ones. This will give a theoretical and experimental evaluation of the scope for making such a standard with fixed pressure points. 7 refs.

**PRESSURE REGULATORS** See Also GAS PIPELINES—Pressure Regulation.

**084921 PRESSURE REGULATORS.** A description is given of pressure regulators which combine the three main components of a control loop into a single device which is simple, dependable, rugged and inexpensive. The self-contained regulator has no adjustments in terms of capacity (reduced valve trim) or of stability (proportional band and reset adjustments). It has a fixed proportional band of about 5%, or a gain of about 20. Descriptions are provided of the most common designs along with their inherent advantages and disadvantages. Factors such as droop or offset, stability and safety, sizing and rangeability, noise and cavitation are discussed. Various types of regulator designs are outlined along with an analysis of the pilot-operated regulator which is a two stage device. Finally, since many applications in pressure control can be handled by either a regulator or a control valve, the author provides an analysis designed to make selection easier. Regulator applications are also given. 14 refs.

Liptak, Bela G. (Bela G. Liptak Associates). *Chem Eng*

(New York) v 94 n 5 Apr 13 1987 p 69-76.

**084922 ELECTRICAL SIGNALS SET AIR REGULATOR'S PRESSURES.** A new type of multi-pressure, electropneumatic regulator has been developed for the precise electronic control of air operated industrial and process equipment. A special strain gage in a closed-loop regulator design gives important operating and reliability advantages. This design precisely controls air pressures, that are either proportional to applied analog voltages and currents or are defined by applied digital signals. It also produces analog and TTL (Transistor-to-Transistor Logic) output signals for continuous pressure monitoring. The regulator operates in any orientation and exhibits high resistance to moisture, vibration, mechanical shock and internal and external contamination. Command signals can be supplied by simple circuitry using potentiometers, rotary switch controller resistor networks or other discrete control devices.

Stefanides, E.J. (Design News, Newton, MA, USA). *Des News (Boston)* v 43 n 12 Jun 22 1987 p 86-88.

**084923 AVAILABILITY OF A PRESSURE REGULATING INSTALLATION ON A CITY MAINS.** Detection of the cause of a Pressure Regulating Installation (PRI) breakdown or fault is done via analytical approach, using the Failure Mode and Effect Analysis, and by looking back over the available records of maintenance operations. To see how far some causes of failure might give rise to dangerous situations, use was made of logical diagrams such as the Incidental Sequences Diagrams and Fault Trees. The availability investigation of a PRI has brought out the difficulty of making a quantitative assessment owing to the scarcity of trustworthy reliability data. This study, in fact, has underscored the extreme individuality of gas distribution plants and the need for a sector data bank operating in such a way as to ensure the constant updating of its reliability data. Qualitative development of the Fault Trees and the consequent analysis of criticality have in any case revealed the existence of second-order minimal cut sets. (Author abstract) 8 refs.

Reliability (Piccinini, N.); Politecnico di Torino, Turin, Italy; Scarrone, M.; Malinverni, E.; Rosti, P. *Reliab Eng Syst Saf* v 20 n 4 1988 p 303-321.

**084924 DYNAMICS OF GAS PRESSURE REGULATOR WITH ATTACHED PIPES.** Dynamics of a pressure regulator with attached pipes has been the subject of numerous studies. In this study, the authors construct a mathematical model of a regulator that takes into account the distribution of the gas parameters with respect to the pipe length. On the basis of this model, an analytic relation for dividing the 'input pipe length-output pipe length' plane into a region of stability 'in the small' and the region of instability is derived. 3 refs.

**Pneumatic Drive**

**084925 MOTORIZED PRESSURE CONTROL.** Pressure regulators maintain a constant output pressure in a system, regardless of changes in flow or inlet pressure. They are used in nearly all industrial air systems, in process industries, petrochemical plants, paper mills, and where the pneumatic signal must be accurately controlled. Regulators can be set manually, with close-coupled or remote pneumatic signals, or with electrical or electronic signals. The latter offer some unique advantages, particularly in remote control or automated applications. A description is given of regulator considerations. The paper highlights the use of computer control in pressure regulates and explains how these advanced electronic controls provide fast and precise control of air pressures.

**084927 NEW TYPE OF DIMENSION MEASURING AND CONTROLLING INSTRUMENT. PNEUMATIC INSTRUMENT WITH PIEZORESISTIVE PRESSURE TRANSDUCER.** In this paper, a kind of precision dimension measuring and controlling instrument, the GLQ type pneumatic instrument with piezoresistive pressure transducer, is introduced. It is small in size, stable, reliable and has wide linear range, large adjustable range in gain and good dynamic characteristic, as well as the advantages of an electropneumatic instrument. All these raise the adaptability of the instrument. The experiments showed that measurement accuracy of the instrument is superior to 2 percent FS. The error of stability of the indication is 1 percent FS. Stable time of transient response is 0.1-0.2 sec, which is 3-5 times smaller than present pneumatic instrument with membrane and bellows. A new type of pneumatic instrument has been provided for precision dimension measuring and controlling. This paper refers to the construction of the instrument, considering problems in design and compensation method of temperature drift of transducer, and gives testing data of static and dynamic characteristics of the instrument. (Author abstract). 4 Refs.

**Design**

**084930 CATHETER-MOUNTED PRESSURE TRANSDUCER USING A FIBER LOOP.** A catheter-mounted fiber optic pressure sensor is described. The sensor consists of a looped fiber; light is coupled into one leg and detected at the other. When the loop bends, microbending in the neck of the loop couples light out of the fiber, resulting in a detectable signal. The catheter was placed in a closed-circuit pumping station in parallel with a strain gauge pressure transducer; the fiber sensor simulated the transducer's output with good fidelity. Aging tests indicate remarkably good reproducibility and stability. (Author abstract) 9 refs.

**Fabrication**

**084931 POLYSILICON-DIAPHRAGM-BASED PRESSURE SENSOR TECHNOLOGY.** The fabrication of capacitive pressure sensors, using silicon integrated circuit processes is described. Polysilicon diaphragms are laid down using the conventional LPCVD technique. A cavity between the polysilicon layer and silicon substrate is created by etching away an intermediate oxide layer. The subsequently sealed cavity with deformable polysilicon membrane decreases in volume with a positive differential pressure between outside and inside. Capacitance changes between an electrode on the membrane and the silicon substrate allow pressure changes to be measured. The batch fabrication technology for microminiature device manufacture is described and electrical characteristics of the device presented. (Author abstract) 2 refs.

**084932 SILICON DIAPHRAGM PRESSURE SENSORS FABRICATED BY ANODIC OXIDATION ETCH-STOP.** Silicon diaphragm pressure sensors have been fabricated by anodic oxidation etch-stop to reduce the pressure sensitivity variation. The diaphragm thickness is precisely controlled by automatic etch-stop in hydrazine-water solution. p-Type piezoresistive elements are fabricated by boron ion implantation on a (100) orientation n-type epitaxial layer. A 5 v positive voltage is applied to the n-type layer of an n/p epitaxial silicon wafer. The thick p-type substrate is then etched off, etching stopped and a thin n-type diaphragm is left. (Edited author abstract) 10 refs.

**Magnetic Field Effects**

**084933 MAGNETIC SENSITIVITY AND MAGNETICALLY INSENSITIVE DESIGN OF TRANSVERSE VOLTAGE PRESSURE VOLTAGE.** As the geometry of a transverse-voltage pressure sensor is similar to that of a Hall element, it is susceptible to the

interference of the magnetic field. From the Boltzmann transport equation in a weak field, the expression of Hall voltage for an inhomogeneously doped layer has been derived. The calculated results for a practical device agree with the experimental data. A method to eliminate the interference of the magnetic field is described. The results are satisfactory. (Edited author abstract). 5 Refs. In Chinese.

## Materials

**084934 PIEZOELECTRIC POLYMER PRESSURE SENSORS.** The use of the piezoelectric material polyvinylidene fluoride (PVdF) in sensors to measure underwater shock wave pressures is described. Its advantages and disadvantages as a sensor material are compared to those of conventional tourmaline sensors. Preliminary results from sensors using this material are shown to compare well with results from tourmaline sensors. Some irregularities are, however, found in the PVdF sensor output, but it is anticipated that these can be eliminated by improved sensor design. (Author abstract) 9 refs.

**084935 MONOLITHIC PRESSURE-FLOW SENSOR.** A novel silicon-based monolithic pressure-flow sensor has been developed. Its operation is based on the piezoresistive effect for pressure sensing and heat transfer for flow sensing. The sensor chip has a thermal isolation structure that is made of an oxidized porous silicon membrane. This structure thermally isolates the heating element located on the membrane from the rim of the chip. The sensor, in which the chip was mounted on a wall of an acrylate plastic pipe, was designed for biomedical applications. Measurements were made at pressures of 0-300 mmHg, water flow rates of 0-7 l/min, and fluid temperatures of 25-45°C. Results are presented. 11 refs.

## Performance

**084936 AUTOMATIC MEASUREMENT OF HIGH PRESSURES.** A manganin pressure transducer has been calibrated for use with a computer-controlled data gathering system. A single polynomial for  $R(p,t)$  reproduces the measurements of pressures up to 350 MPa and temperatures from 0 to 40°C. The repeatability obtained in the initial calibration of  $R(p,t)$  was 12 ppm. An uncertainty of 0.1 K would result in a variability in  $R(p,t)$  of, at most, 3 ppm, but over most of the temperature span it would be much smaller because of the favorable temperature characteristic of manganin. Pressure measurements are accurate to 0.1 MPa, and probably repeatable to better than this. This corresponds to an uncertainty of less than 2.5 ppm in  $R(p,t)$ . (Edited author abstract) 12 refs.

**084937 DEVELOPMENT LINES FOR AUTOMATIC PRESSURE SENSORS.** Simple and reliable loaded-piston manometers represented the basic means of transmitting the pressure unit in the range 0.1-1000 MPa in the 1940s to 1960s, and these always included devices

for setting up the pressure and connecting test instruments, i.e., they were not simply standard instrument but instead test systems. However, they had one major disadvantage: they were laborious to use, and considerable physical stress was required at pressures above 10 MPa on account of the handling of heavy loads and the manual compression involved. At the end of the 1950s, large-scale gauge production was initiated, and it became desirable to mechanize the main manual operations. An automatic pressure sensor was developed in the USSR. These sensors were made in batches of 16 and used in production. The sensor was an automated loaded-piston gauge giving the range 0.25-30 MPa for test manometers of accuracy class 0.2%. For each standard range, it provided three pressure steps, not including zero. More recent developments in Russia and in the United States are reported. 6 refs.

Kipnis, A.M. *Meas Tech* v 30 n 4 Apr 1987 p 359-361.

**084938 METHODS OF DETERMINING THE DYNAMIC CHARACTERISTICS OF PRESSURE TRANSDUCERS.** Variable-pressure transducers VPT are used in monitoring these processes, which are usually of special and narrowly defined purpose. In most cases, the errors are determined only under static conditions, since there are no standard methods of estimating dynamic characteristics. This means that there may be deviations from unified measurements, so it is important to devise methods for determining these dynamic characteristics. The proposed technique is based on an adaptive method of determining the complete dynamic characteristics of means of measurement which enables one to use standard test signals to derive analytic expressions for the transfer function and for the pulse, transient, and amplitude-frequency characteristics. The basic method consists in using the response of the test instrument to a standard signal to find the optimum structure for the transfer function. A multistep adaptive procedure is used, which includes surveying transfer functions of increasing complexity from step to step and deriving the optimal coefficients in the transfer function at each step. 5 refs.

**084939 CERAMIC DIFFERENTIAL-PRESSURE TRANSDUCER.** The differential-pressure transducer is made completely of alumina, and is therefore resistant to practically all corrosive fluids used in process engineering. The transducer has a single liquid-filled chamber, isolated by two diaphragms from the fluids whose differential pressure is to be measured. The deflections of these diaphragms are measured by a capacitive method. Four electrodes, applied to the two diaphragms and on opposite sides of a central plate, form two capacitors. The measured differential pressure is proportional to the difference of the reciprocals of their capacitances. This difference is affected, however, by the temperature of the liquid in the transducer. The effect is compensated by using the sum of the reciprocals of the capacitances, which is proportional to the temperature. The linear temperature compensation is produced by an electronic circuit that includes operational amplifiers and a feedback loop. This circuit and the ceramic transducer are incorporated in the differential-pressure transmitter, which is now on the market in six models with different measuring ranges. Experimental versions are now ready of a differential-pressure transducer for laboratory use, in which nonlinear temperature effects can also be compensated. A method is being studied for transmitting the results of measurements along optical fibers. (Edited author abstract) 5 refs.

## Pistons

**084943 EFFECTS ON THE PARAMETERS OF A PISTON PRESSURE GAUGE FROM THE PRESSURE DISTRIBUTION IN THE PISTON PAIR.** The pressure distribution influences the effective area of a noncylindrical piston pair (all piston pairs are noncylindrical), and pertinent theoretical and experimental studies have been made, which enables one to reduce the deformation error in high-pressure piston gauges by more than two orders of magnitude, namely to thousandths of a percent. No study has been made of the effects of the pressure distribution on other parameters of these gauges. An attempt is made to fill this gap. 5 refs.

Borovkov, V.M. *Meas Tech* v 30 n 4 Apr 1987 p 361-364.

## Selection

**084944 PICKING THE PERFECT PRESSURE TRANSDUCER.** Innovations in pressure transducer technology have resulted in improved designs and reduction of the cost of pressure measurements. These advances, coupled with the trend toward factory automation and computer control of plant systems, have generated many new applications for pressure transducers, some of which are discussed. (Edited author abstract).

Loth, Steven A. (Imo Delaval Inc, Pasadena, CA, USA). *InTech* v 35 n 7 Jul 1988 p 37-40.

## Stability

**084945 ZERO STABILITY OF DISPOSABLE AND REUSABLE PRESSURE TRANSDUCERS.** Zero stability tests were performed on contrasting, commercially available, blood pressure-transducer systems. One system was based on a brand of disposable transducer. The others employed one brand of reusable transducer with and without samples of two different brands of compatible disposable domes. Drift was measured at atmospheric pressure over 3-hr periods. Drifts with the disposable transducers and with the bare reusable transducers were small, ranging from -2 to +2 mm Hg over 3 hr. However, the drifts of the reusable transducers with domes were significantly greater, ranging from -11 mm to +5 mm Hg. The disposable transducers did not drift significantly after the first half hour, although the reusable transducers with domes continued to drift. In addition, one brand of disposable dome produced inaccurate calibrations with the reusable transducer. The methodology of drift measurement and analysis should be practical and useful in other settings and with other brands of transduc-

ers. In general, the results indicate that periodic zeroing is still a clinically important procedure, and it is a worthwhile effort prior to treatment decisions based on pressure readings. (Author abstract) 5 refs.

## Switching

**084946 PRESSURE SWITCHES - AN INTRODUCTION.** Pressure switches are used in a variety of applications. For example, a gage sensor can be used to indicate the presence of a work piece on a vacuum check or holder, or in a multiple switch point system to maintain a constant tank pressure. The use of pressure switches is widespread and virtually unlimited. This article gives some basic switch configurations and the design details for low cost, reliable, semiconductor sensor pressure switches.

**084947 PRESSURE VESSEL AND PIPING TECHNOLOGY: TWO DECADES OF PROGRESS AND FUTURE CHALLENGES.** The organizational and technological advances of the last two decades in the U.S. Pressure Vessel and Piping (PVP) Technology are first traced. Highlights of growth in the major organizations supporting PVP technology: ASME Boiler and Pressure Vessel Code, Pressure Vessel Research Committee, and the ASME Pressure Vessels and Piping Division, are given, along with highlights in the technological advances in Design Analysis, Materials and Fabrication. Future challenges in key technological areas for PVP engineers are discussed, including the role of the PVP engineer in developing technologies such as BIOTECHNOLOGY, SUPERCONDUCTIVITY, MICRO-ELECTRONICS, ENERGY, ENVIRONMENTAL ENGINEERING, and ADVANCED MATERIALS. This paper concludes with a discussion of two major institutional challenges of our time: winning public acceptance of technology; competitiveness and foreign trade. (Author abstract) 7 refs.

**084948 COMPUTER AIDED DESIGN OF SADDLE SUPPORTS FOR HORIZONTAL PRESSURE VESSELS.** Computer aided design of saddle supports for chemical process equipment has been presented. Though apparently looks simple in construction, the design of saddle supports involves a large number of tedious trial and error computations. Various combinations of the design parameters such as the included angle of the saddle (TETA), saddle width (B), location of the saddle from vessel end (AS), the stiffener requirement and the required area of ring stiffener (AR), the width (W) and thickness (TI) of reinforcing backing plate (if required) between the saddle and the vessel shell, require to be tried to propose an optimum choice for final design. A consolidated CAD program as discussed in this paper shall therefore be of advantage for determining an optimum combination of the above-mentioned parameters. The CAD flow-sheet has been prepared in a versatile and flexible manner and it has been checked and verified on EC-1045 computer. (Author abstract) 3 Refs.

**084952 RESULTS OF ACOUSTIC EMISSION DURING MECHANICAL AND THERMAL LOADINGS OF VESSEL COMPONENTS AND THEIR FRACTURE MECHANICAL INTERPRETATION.** AE measurements are presented which were performed at pressure vessel components during different loadings: thermal shocking hydrotest, cyclic loading. The tests were executed with the IZP AE system. With this it is possible to locate the AE sources and to identify two source mechanisms: crack growth and crack flank friction. The AE results are discussed and compared with the results of calculations about the residual stress in a clad vessel wall: AE signals originating from crack growth process are detected very sensitively. During thermal shock a lot of crack border friction occurs in consequence of compressive stresses on the crack flanks. However, during the hydrotests no crack border friction appears, because the crack flanks are mainly under tensile stresses. (Author abstract) 6 refs.

Codes See Also CYLINDERS—Fabrication.

**084953 SAFE AND COST-EFFECTIVE DESIGN OF PRESSURE VESSELS.** This paper discusses the design of new pressure vessels. The discussions conclude that: 1. The contemporary design method can be strenuous, and the as-built thickness(es) (less CA) may be uneconomically distant from the optimum. Computerization does not necessarily bring them closer to the optimum. 2. More realistic thinning rates and ratios would significantly improve future vessel maintenance costs. 3. The employment of the ECS Boundary Curves can give optimum thickness for a given vessel/nozzle junction. 4. Since the boundary curves remain unchanged for an intended service-life, the S/H-N graph complements the U-1A form. This graph can be the "birth certificate" for the vessel on which the owner of the vessel could chart his actual thinning as years of service pass.

## Concrete

**084956 BEHAVIOUR OF PRESTRESSED CONCRETE CONTAINMENT STRUCTURE UNDER EXTREMELY LOW TEMPERATURE.** Prestressed concrete has been recognized as an excellent containment structure for storages of low temperature liquid such as LNG (-164°C). The study was conducted to evaluate mechanical properties of prestressed materials. Emphasis was laid on the evaluation of material and structural behavior in terms of ductility and liquid tightness. The experimental research was divided into five phases. Phase 1 tested and evaluated the notch sensitivity of prestressing wire, while Phase 2 examined the ductility of anchorage materials. In Phase 3, full size prestressing tendon systems of 12T 15.2 were subjected to static and cyclic loading under low temperature conforming to the FIP recommendation. Phase 4 examined the structural behavior of prestressed concrete beams under the impact loading at low temperature. Phase 5 tests the response of prestressed concrete beams subjected to various axial stresses and temperature gradient. Prestressed concrete and its steel materials have shown superior mechanical properties for cryogenic storage structure. (Edited author abstract) 13 Refs. In Japanese.

## Cooling

**084957 THERMALLY STRESSED STATE OF HIGH PRESSURE VESSELS UNDER CHILLING AND SUPERCHARGING CONDITIONS: COMMUNICATION 4. COMBINED CHILLING CONDITIONS.** Three variants for conditions of combined chilling (preliminary purging of the vessel with a gaseous and its subsequent filling with a liquid coolant - nitrogen) of thick-walled HP vessel are calculated. Results of the calculation are presented. General regularities of the change in nonstationary heat and thermoelastic stressed states in the process of chilling during a long period of time as dependent on conditions of thermal and force loading are established. Rational conditions of the vessel chilling are determined which provide the required rate of the vessel chilling within the time range of 0 < t < 6 h and mild conditions of the thermal and force loading. (Edited author abstract) In Russian. 4 refs.

## Crack Propagation

**084958 STRESS INTENSITY FACTORS FOR A PRESSURIZED THICK-WALLED CYLINDER WITH RADIAL CRACKS OF UNEQUAL LENGTH.** The loading capacity of many industrial pressure vessels is often impaired by the gradual degradation of their internal surfaces under the combined action of high pressure pulses and environmental factors. As a rule, this degradation leads to microcracking, thereby creating potential sources of macroscopic fracture due to fatigue mechanisms. Furthermore, these cracks tend to grow unevenly as a result of the stochastic nature of the material's matrix and the varying environmental conditions. In order to evaluate the influence of crack length variance on the stress intensity factors  $K_I$ , for large arrays of radial cracks emanating from the bore of the cylindrical vessel, a 'two crack length level model' is applied. In this model the array of radial cracks is assumed to consist of two subarrays each of which comprises cracks of constant depth, though the two subarrays themselves may bear different crack lengths. All cracks are evenly spaced while crack length alternates. A few sets of calculations were performed. 4 refs.

Arone, R. (Technion, Haifa, Isr); Perl, M. *Int J Fract* v 34 n 4 Aug 1987 p R75-R78.

**084959 THREE-DIMENSIONAL RUPTURE ANALYSIS OF STEEL LINERS ANCHORED TO CONCRETE PRESSURE AND CONTAINMENT VESSELS.** Steel liners or plates are anchored to concrete pressure and containment vessels for nuclear and offshore facilities. Due to extreme loading conditions a liner may buckle due to the pull-out or shearing of anchors from the base metal and concrete. Under certain conditions attributed to loadings, liner metal deterioration and cracking of concrete behind the liner, the liner may fail by rupture. This paper presents a three-dimensional analysis of steel-concrete elements, using finite element in which a provision is made for liner instability, anchor strength and stiffness, concrete cracking and finally liner rupture. The analysis is tested first on an octagonal slab with and without an anchored steel liner. It is then extended to concrete pressure and containment vessels. The analytical results obtained are compared well with those available from the experimental tests and other sources. (Author abstract) 37 refs.

## Cracking

**084960 THERMAL, IRRADIATION AND CYCLIC LOADING ANALYSIS FOR STRESS FATIGUE CRACK IN REACTOR VESSELS.** The thermal, irradiation and cyclic loading analysis for stress fatigue crack (SFC) of the base and weld materials of LMFBR (liquid metal fast breeder reactor) and LWR (light water reactor) pressure vessels is theoretically carried out based on experimental data. The power function and exponential function crack (rate) laws and the SFC theory are introduced and postulated for the stress intensity factor,  $K_I$ , or the effective stress intensity factor versus the fatigue crack growth rate in the vessel materials. Experimental data of austenitic stainless steels 304 and 316, nickel alloy Inconel 600, and low-carbon alloy steels A516 and A533 of the LMFBR and LWR pressure vessels were respectively computedly measured, examined and analyzed, and then plotted for either power function crack rate and/or exponential function crack law. (Edited author abstract) 24 refs.

## Deformation

**084962 INVESTIGATION OF DEFORMATIONS AND FATIGUE RESISTANCE OF CYLINDRICAL PRESSURE VESSELS.** It is shown that distribution of tangential strains under cyclic loading of pressure vessels produced by 30KhGSA steel is heterogeneous in length. Fatigue resistance in vessels is determined by the sites with the highest values of accumulated strains along the perimeter of a cylindrical part. The fatigue curves are obtained for the experimental vessel and for vessels with the length differing from the experimental one. (Author abstract) In Russian. 4 refs.

Babitsky, M.S. *Probl Prochn* n 9 1987 p 55-57.

**Design** See Also NUCLEAR REACTORS, BREEDER —Pressure Vessels; STRESSES—Analysis.

**084963 RATIONAL DESIGN OF THIN-WALLED PRESSURE VESSEL ENDS.** Optimal contours for heads of cylindrical pressure vessels are discussed. As opposed to the common method of preventing buckling in pressure vessel ends by means of increased wall thickness or local reinforcements, this paper proposes a design for 'buckle-free' shapes in which the contour is established/adjusted so as to ensure stable behavior. A previous analysis by the authors, in which compressive stresses were eliminated, is extended so as to take into account the actual flexural rigidity of the wall. The shapes obtained from such buckle-free designs appear to be similar to standard ellipsoidal and torispherical ends and should be acceptable from various design and aesthetic viewpoints. (Author abstract) 14 refs.

**084964 ZEITLICHER DRUCKVERLAUF BEI EXPLOSIONEN ALS GRUNDLAGE ZUR AUSLEGUNG VON BEHAELTERN UND APPARATEN.** [Time-Dependent Behavior of Pressure in Cases of Explosions: A Basis for Design of Pressure Vessels and Apparatus]. Knowledge of the maximum explosion pressure is important for design of pressure vessels subject to danger of explosion. For non-spherical geometries or plant-internal pressure relief, the maximum explosion pressure has to be calculated from the time-dependent pressure caused by a chemical reaction in the vessel. Therefore, a set of ordinary differential equations was solved numerically by means of the method of differences. Examples are drawn from known experimental studies. Turbulence effects are also considered. As a result, an analytical relationship is derived which gives the necessary pressure relief area. Finally the results are compared with those of available formulas. Deviations are explained in detail. (Edited author abstract) 22 refs. In German.

**084965 OPTIMIZED PRESSURE VESSEL DESIGN WITH SPECIAL RESPECT TO OPERATING CONDITIONS.** Stress calculations for pressure vessels must be performed to demonstrate that at least minimum requirements of the relevant technical code are met. With stress analysis it is demonstrated that component fatigue

life can be influenced to a considerable extent by design and manufacture. Practical examples are provided to show the influence of stress concentrations and expansion constraints as well as the importance of using the proper weld seam and the influence of manufacture-based stress concentrations such as undercuts, edge displacements and surface influences. It is shown that in many cases tremendous improvements in component performance and component life can be gained at low expense if simple design principles are observed. (Edited author abstract)

Gerlach, H.D. (Rheinisch-West-Faelischer Technischer Ueberwachungs-Verein eV, Essen, West Ger). *Int J Pressure Vessels Piping* v 31 n 4 1988 p 285-293.

**084966 PROBLEM OF DESIGNING DOUBLE-CHAMBER GAS PRESSURE VESSELS.** The use of reaction gases under pressure offers new possibilities for hot isostatic processing: the manufacturing of articles with new or enhanced properties, shorter process time, and improved process productivity. However the processing pressure vessel must be protected against the reaction gases. One approach is to have a two-chamber gas pressure vessel, the outer chamber of which contains the thermal insulating hood and the heating element, and the inner chamber of which contains the workpiece and the reaction working medium. There are two fundamentally different designs for the inner chamber: the first type must be removable from the pressure vessel to allow loading of workpieces; the second type can be placed directly in the working space of the pressure vessel. 6 refs.

**084967 DISRUPTIVE FAILURE OF PRESSURE VESSELS: PRELIMINARY DESIGN GUIDELINES FOR FRAGMENT VELOCITY AND THE EXTENT OF THE HAZARD ZONE.** In the event of an accident, an industrial plant must be capable of being shut down in a safe, controlled manner. Thus, when a plant containing high-pressure fluids is being designed, the potential damage to essential shut-down equipment resulting from rupture of the pressure envelope must be assessed and, where necessary, protection provided. For example, pressure vessel rupture may generate missiles; i.e., sections of the pressure envelope become detached and are accelerated to significant velocities by the expanding fluid contents. An assessment of the consequences of pressure vessel rupture must therefore include estimates of the likely extent of the missile impact zone and the potential damage to equipment within that zone, which are both functions of the missile velocity. This paper describes preliminary guidelines for defining the velocity of the various types of missile which can be generated by pressure vessel failure. (Edited author abstract) 15 refs.

**084968 OPTIMAL SOLUTIONS DECISION OF EQUIVALENT STRESS FUNCTION WITH RESPECT TO TWO VARIABLES FOR THE AUTO-FRETTAGED VESSEL.** The formulae of equivalent stress were constructed in other papers. Some methods of optimization also were proposed. To obtain the optimal solution of equivalent is the key in the engineering design of autofrettaged vessel of high pressure. Therefore, this paper investigates some properties of optimal solutions and the existence of optimal solutions for the equivalent stress function with respect to two variables by the theory of convex function analysis and multiple objective programming. ## Elastoplasticity

**084969 ELASTIC-PLASTIC ANALYSIS OF HYDRIDE BLISTERS IN ZIRCALLOY-2 PRESSURE TUBES.** The possibility that stresses might be produced as a consequence of expansion resulting from the transfor-

mation of zirconium to zirconium hydride in the form of blisters was investigated. Parametric elastic-plastic finite element analyses were performed because the physical properties near the blister were not clearly defined. Results show that significant stresses can arise from the volume expansion of hydride blisters, being largely compressive within the blister, tensile outside. (Author abstract). 7 Refs.

## Evaluation

**084970 EVALUATION OF REACTOR VESSEL BELTLINE INTEGRITY FOLLOWING UNANTICIPATED OPERATING EVENTS.** Using these simplified ASME code guidelines, a utility can determine within hours whether it can safely return a reactor vessel to service after a transient has caused operation beyond the specified pressure-temperature limits. The guidelines, endorsed by NRC, include criteria both for quick screening and for more-detailed evaluation of pressure vessel integrity. Low-temperature overpressure (LTOP) and pressurized thermal transient (PTT) events sometimes cause reactors to operate beyond those limits. The study produced screening criteria for quickly assessing the integrity of the reactor vessel after a LTOP or PTT event. In addition, it yielded a fracture mechanics evaluation procedure and acceptance criteria for a more detailed assessment. (Edited author abstract)

**084971 CREEP RELAXATION IN MULTILAYER WRAPPED VESSELS.** One of the common methods of construction of vessels for high to ultra-high pressure applications is the wrapping technique. In this method, relatively thin plates (normally in the range of 6 mm) are rolled to proper curvature, wrapped around the core or the preceding layers and then welded. In this fashion, a prestress is gradually built in the cylinder wall which would compensate and moderate the extreme stresses due to internal pressure. Relying on such prestress, however, should be done only with careful consideration of stress relaxation that will take place while the vessel is in service, especially in high temperature services. In this paper, the initial stresses due to wrapping are obtained. These stresses are due to shrinkage of the weld as well as the plate affected by the heat of welding. The power function stress-creep strain rate is employed to predict the relaxation of interface pressure between any two adjacent layers. (Edited author abstract) 11 refs.

**084972 STATISTICS OF PRESSURE VESSEL AND PIPING FAILURES.** This paper attempts to present a broad overview of failure statistics for both pressure vessels and piping. The pressure vessel case is more straightforward because each vessel is a discrete component. With piping the situation is much more difficult. Piping systems consist of a number of components varying markedly from system to system. While there is a large body of fairly well-defined statistics for pressure vessels in Germany, the United Kingdom and the United States, the same cannot be said for piping. As a result, piping statistics in this section are limited to nuclear systems with the assumption that they are extrapolatable to non-nuclear systems. 17 Refs.

**084973 PROBLEMS OF INCREASING LOW CYCLE FATIGUE RESISTANCE OF HIGH PRESSURE VESSEL STUDS.** A new variant of engineering estimation of elastic stress concentration coefficients in the threads of 10,200 mm diameter studs in a pair with compressive nuts is suggested taking account of standard geometrical parameters of the threads. It is shown that the pitch is a key parameter of the thread geometry in the stud-nut joint. Results studies of low-cycle fatigue (LCF) of M12 threads with different thread geometry are presented. It is shown that a decrease in the thread pitch of M12 studs considerably increases the nut joint life. The scale factor and thread geometry are studied for their effect on LCF of 38KhN3MFA steel nut studs. Results of the study are presented. It is established that the effect of the thread geometry on LCF of large-diameter studs is less noticeable than on the small diameter ones. (Edited author abstract) In Russian. Refs.

**084974 LATE-EVENT VISCOPLASTICITY IN WIDE-PLATE CRACK-ARREST TESTS.** A primary objective of the crack-arrest studies being conducted by the Heavy-Section Steel Technology (HSST) program is to understand pressure vessel conditions that would initiate growth of an existing crack and conditions that would lead to arrest of a moving crack. In meeting this objective, the HSST program is generating crack-arrest data over an expanded temperature range through tests involving large cylinders, pressure vessels and wide-plate specimens. This paper describes the portion of those studies that relate to the installation of two viscoplastic constitutive models and several proposed fracture criteria into the ADINA finite element program. **084976 MATHEMATICAL MODEL FOR DETERMINING THE THERMOHYDRAULIC PARAMETERS OF BOILING COOLANT WITH LOSS-OF-COOLANT FROM A VESSEL.** The investigations of thermodynamic processes in emergency situations at nuclear power stations should there be loss-of-coolant accidents have led to the formulation of a number of programs describing these processes. There is particular interest in studying the effects of separation of coolant with small leakages, when residual heat release has a considerable effect on characteristics of the process of escape of boiling liquid. To describe this effect a mathematical model was developed and a calculation program written which enabled allowance to be made for residual heat release with escape of two-phase mixture from a vessel. 7 refs.

**084980 ASSESSMENT OF ALTERNATE STEELS FOR WELDED PRESSURE VESSELS.** The objective of this project was to identify alternate steels to the standard SA 516Gr70 steel for pressure vessel fabrication. The Welding Institute of Canada (WIC) Rigid Restraint Cracking Test (RRC) was modified to cope with steels thicker than 50mm and used to establish minimum preheat/heat input conditions necessary to avoid heat-affect zone (HAZ) cracking in the high restraint conditions of the WIC test. After a world-wide survey of steelmaking technologies and a listing of available steels by Chinook Fuels of Calgary, eight steels are assessed in the original contract. No individual steel better than a particular SA 516Gr70 was found. Further testing at the University of Alberta was carried out on five more steels. Four of the new contract steels showed better cracking resistance than the standard SA 516Gr70 after preliminary testing. Continued testing revealed that a normalizing heat treatment on several original contract steels improved their resistance to HAZ-cracking. (Edited author abstract) 6 refs.

**084981 NEW MANUFACTURING TECHNIQUES OF LARGE FORGED SHELL RINGS FOR PRESSURE VESSELS.** A 250 ton hollow ingot was made for experimental purposes so that the properties of a large-sized hollow ingot could be simulated. The investigation results indicated that this ingot was suitable for forged shell rings of nuclear reactor pressure vessels (RPV). They were used in the manufacture of forged shell rings for an RPV of a 1300 MW type PWR and for an RPV of an 1100 MW type BWR using basic oxygen furnace, RH degassing, hollow ingot-making process. These shell rings had less segregation and clean inner surfaces which are attributed to the homogeneity of the hollow ingot. (Author abstract) 6 refs.

**084982 PLASTIC DEFORMATION AND FRACTURE BEHAVIOUR OF 2 1/4 Cr-1 Mo PRESSURE-VESEL STEEL WITH BAINITIC AND BAINITIC-FERRITIC MICROSTRUCTURE.** During the heat treatment of steel plates and forgings with large thicknesses, microstructures with various volume fraction of ferrite can appear. Plastic properties and fracture behavior of these mixed microstructures are a function of ferrite content. The influence of ferrite content in the range from 0% to 54% in the bainitic-ferritic microstructure on mechanical properties and fracture behavior of 2 1/4Cr-1 Mo steel was examined. The yield stress was found to decrease linearly with the volume fraction of ferrite. The tensile strength was independent of ferrite content up to 25 percent, after which the tensile strength decreased as well. By the Charpy test it has been found that there exists the critical ferrite content - 25 percent - in a mixed microstructure, at which the propagation and initiation transition temperature attain the highest values. The fracture toughness tests pointed out the same results. (Edited author abstract). 28 Refs.

**084984 BETRIEBSNAHE SCHADENSERKENNUNG MIT HILFE DER HOLOGRAFISCHEN INTERFEROMETRIE UND EINES DOPPELIMPULSLASERS.** [Holographic Investigation on Failure Mechanisms in Homogeneous Materials]. There is a relation between defects occurring in the wall material of pressurized equipment and deformation of the wall surface under load. If the deformation at the surface exceeds 35 nm, it is possible to use holographic interferometry for detection. The method is applicable to pressure vessels if the holographic fringe pattern is related quantitatively to the size of a failure. This report presents experimental results which give the relation between the perturbation of the holographic fringes and the size of different kinds of failures. The size of the smallest detectable failure is smaller than the critical size of a flaw in the material. (Edited author abstract) 5 refs. In German.

**084986 USING AE MONITORING FOR ON-LINE CRACK DETECTION.** On-line acoustic emissions (AE) monitoring of a feed nozzle on a heat cracking tower and butt weld seams between the piping and flanges in the high pressure reforming process of an ammonia plant was conducted with a two-channel waveform recorder and an AE analyzer. To avoid degradation of the PZT sensors from high temperature, two sensors were separately attached to the cold top-surfaces of two wave guides through which the feed nozzle and the butt weld seam were monitored for cracking and leaking under operating conditions. Inspection and X-ray examination, after shut down, proved that on-line AE monitoring was effective.

## Production

**084988 PRODUCTION EQUIPMENT FOR SPIRALLY WOUND LAYERED VESSEL.** Spirally wound layered vessels are a type of multi-layered vessel used as high pressure vessels in chemical plants, etc., and consist of an internal shell around which hoop steel is wound spirally in layers. Stable, automatic winding and high-speed welding of hoop steel are major considerations to ensure efficient production of high-quality spirally wound layered vessels. For these purposes, the hoop steel must be wound with a uniform gap between the hoop steel and minimum clearances between the layers. In order to develop winding equipment which will meet these requirements, tests were carried out to determine which parameters should be controlled and by what method. As a result, it was found that if hoop steel is controlled at a proper angle, both the gap between the hoop steel and the clearances between the layers will be within the target values and the ASME requirements. (Author abstract) In Japanese. 2 refs.

## Radiation Damage

**084989 RADIATION-INDUCED EMBRITTLEMENT IN LIGHT WATER REACTOR PRESSURE VESSELS.** In operating light water reactor (LWR) commercial power plants, neutron radiation induces

embrittlement of the pressure vessel (PV) and its support structures. As a consequence, LWR-PV integrity is a primary safety consideration. Recent LWR-PV benchmark experiments are analyzed in this paper. On this basis, it is established that an exponential representation accurately describes the spatial dependence of neutron exposure in LWR-PV. Implications produced by this simple exponential behavior are explained and trend-curve models for the prediction of PV embrittlement are derived. These derivations provide for a clearer understanding and assessment of the assumptions underlying these trend-curve models. It is demonstrated that LWR-PV embrittlement possesses significant material dependence. (Edited author abstract) 25 refs.

## Safety Codes

**084990 PREDICTIVE MAINTENANCE OF PRESSURE VESSELS.** In-service corrosion/erosion data can be computer-analyzed to prove Code-compliance and predict the remnant life of vessels. Measurement of thickness(es) for vessels in service is therefore to be strongly encouraged. API 510 makes valuable recommendations in this respect. Thickness measurements can now be made by ultrasonics without interfering with your production process. But that's just the beginning. Subsequently, the measured wall thicknesses must be used in an engineering evaluation to provide answers to: 1. Is the vessel Code-compliant or non-compliant today? 2. How soon should the next set of measurements be taken? 3. How much thickness is left for safe continued use? The author divides the discussion into several parts: how the evaluation of in-service vessels is performed at present; how it could be improved by using the concept of 'minimum thickness' and by computerisation; and finally the practicalities of setting up a predictive maintenance programme.

Grosshandler, S. *Process Eng (London)* v 68 n 8 Aug 1987 p 27-29, 31.

**084991 EMERGENCY RELIEF SYSTEM DESIGN FOR REACTIVE AND NON-REACTIVE SYSTEMS: EXTENSION OF THE DIERS METHODOLOGY.** Simple mechanistic models for reactive and non-reactive chemicals are summarized. The DIERS methodology has been extended as well as simplified to account for vapor disengagement and frictional effects including laminar flow conditions-both principal objectives of the DIERS program. Gassy systems involving non-flashing two-phase flow are also discussed including a simple procedure for assessing the vent size without requiring specific knowledge about tempering conditions. Non-reactive systems involving fire exposure are discussed including atmospheric as well as high pressure systems. A possible preventive measure for boiling liquid expanding vapor explosions (BLEVE) is suggested. (Edited author abstract). 29 Refs.

**084992 LIFE ASSESSMENT TECHNIQUES APPLIED TO A 1% Cr-0.5%Mo PRESSURE VESSEL AFTER 95,000 HOURS SERVICE.** A 1% Cr-0.5% Mo primary superheater outlet header failed through cracking of the central girth weld after 94 835 hours of service. The header was replaced and made available for study as it was thought that a residual life analysis may provide an indication of the life that could be expected from similar headers in the remaining boilers of this power station. The life of this header was firstly assessed using the boiler operating history in conjunction with the Life Fraction

Rule. It was then assessed using accelerated creep rupture testing. Problems with each method are discussed. Stub-tube hole ovality is described as an 'in situ' method of life assessment; however, although results indicate that the header has sustained some creep, these results cannot be interpreted in a quantitative manner. A microstructurally based method for determining average operating temperature of components is also mentioned. (Edited author abstract) 9 refs.

Coade, R.W. (State Electricity Commission of Victoria, Aust.). *Mech Eng Trans Inst Eng Aust V ME 11 n 2 Jul 1986 p 104-111.*

**084993 DIAMETRAL STRAIN RESPONSE AND MICROSTRUCTURAL YIELDING MECHANISMS OF A BAINITIC PRESSURE VESSEL STEEL.** Unexpected trends of diametral strain range response have been recorded for annealed bainitic Cr-Mo-V pressure vessel steel at room temperature and moderate strain amplitudes. Stress and diametral strain response were also recorded for three harder heat treatment variants, but they behaved as expected. The alloy is strengthened by a carbide dispersion and a dislocation network, both of variable density. The unexpected diametral strain response is suggested to be associated with yet unknown macroscopic effects of particular observed microscopic mechanisms of slip. These mechanisms of slip can be analyzed with a model for dispersion strengthening which expresses the connection between nominal dislocation activity and the plastic and elastic components of elongation. Additional aspects of the subject are discussed. (Edited author abstract) 17 refs.

**084996 STATUS OF RESEARCH ON ENVIRONMENTALLY ASSISTED CRACKING IN LWR PRESSURE VESSEL STEELS.** This paper reviews collabora-

tive work that has the objective of defining, from first principles, the environmentally assisted crack growth rates in the Type A533B or A508 low-alloy steel/water system at 288°C under static and cyclic loading conditions. These theoretical rates are then used to assess the validity of the current ASME XI life evaluation code. The investigations, which were conducted by members of the International Cyclic Crack Growth Rate Group, have centered around (a) defining a working hypothesis for environmentally assisted cracking, (b) determining the nature and magnitude of crack tip environments and reaction rates that are pertinent to the crack advance hypothesis, (c) quantitatively validating a hypothesis by comparing observed and theoretical values, and (d) using the qualified mechanism to evaluate the validity of current life-evaluation codes for environmentally assisted crack propagation. It is concluded that, on the basis of the bulk of present data, the slip dissolution (film rupture) model seems to be quantitatively the most valid crack advance mechanism for this system at 288°C. (Edited author abstract) 104 refs.

Ford, F.P. (GE Corporate Research & Development Cent, Schenectady, NY, USA). *J Pressure Vessel Technol Trans ASME v 110 n 2 May 1988 p 113-128.*

**084997 DETERMINATION OF CRACK ARREST TOUGHNESS AT HIGH TEMPERATURES USING COMPACT SPECIMENS.** In order to determine the influence of the test temperature on the crack arrest toughness, investigations were carried out on pressure vessel steels of various strength and toughness up to the upper-shelf of the Charpy V-notch impact energy ( $C_V$ -energy). The tests were conducted on the basis of the proposed ASTM test method for ferritic steels with modified wedge-loaded compact specimens. The thickness ranged from 0.75-6.69 in. (19-170 mm), the in-plane dimensions from 3.94-15.75 in. (100-400 mm). The comparison with the reference curves of the American and German guidelines showed significant discrepancies at high temperatures. (Author abstract) 12 refs.

**084999 FRACTURE TOUGHNESS AND CRACK GROWTH RESISTANCE OF PRESSURE VESSEL PLATE AND WELD METAL STEELS.** Compact tension specimens were used to measure the initiation fracture toughness and crack growth resistance of pressure vessel steel plates and submerged arc weld metal. Plate test specimens were manufactured from four different casts of steel comprising: aluminum killed C-Mn-Mo-Cu and C-Mn steel and two silicon killed C-Mn steels. Weld metal test specimens were extracted from five weld joints of Unionmet No. 2 weld metal. The welds were of double V butt geometry having either the C-Mn-Mo-Cu steel (three weld joints) or one particular silicon killed C-Mn steel (two weld joints) as parent plate. On the upper shelf, a multiple specimen test technique was used to obtain crack growth data which were analyzed by simple linear regression to determine the crack growth resistance lines and to derive the initiation fracture toughness values for each test temperature. These regression lines were highly scattered with respect to temperature and it was very difficult to determine precisely the temperature depen-

dence of the initiation fracture toughness and crack growth resistance. (Edited author abstract). 8 Refs.

**085003 INFLUENTA PARAMETRILOR GEOMETRICI AI SECTIUNII ASUPRA STARII DE TENSIUNE DIN INVELISURILE CILINDRICE OVALIZATE SOLICITATE CU PRESIUNE INTERIOARA.** [Influence of Geometrical Parameters of the Section on the Stresses in Ovalised Cylindrical Tubes Under Internal Pressure]. The calculation relations obtained by means of a simplified model are transcribed via dimensionless parameters with a view to using them in the study of stresses produced by the internal pressure in ovalised cylindrical tubes. The conclusions derived from the application of these relations to shells having different diameters, wall thickness and ovalizations led to the

elaboration of a simple methodology for the calculation of stresses generated by this particular form of the cross section. (Author abstract) In Romanian. 3 refs.

**085004 STRESS ANALYSIS OF PRESSURE VESSELS WITH UNIFORMLY SPACED LUGS.** Stresses and displacements in circular cylindrical shells having square and rectangular lugs have been studied in this paper. The analysis presented here is based on finite element technique using 17-node doubly curved shell elements. Numerical computations have been performed for the case of longitudinal moments applied at discrete points around the circumference of the vessel. Four identical lugs uniformly spaced around a parallel have been considered. Results have been generated for several cases with different lug sizes and  $t/a$  ratios. (Author abstract) 11 refs.

**085005 PRESSURE VESSEL RESEARCH COMMITTEE: WRC - 50 YEARS OF PROGRESS THROUGH COOPERATIVE RESEARCH.** The Welding Research Council (WRC) Bulletin No. 107 and Bulletin No. 297 are two of the most important design guides ever published for the design of pressure vessels. Widely used in the design of attachments and nozzle connections, they have become indispensable tools in recent years. WRC-107 and WRC-297 are invaluable due to their combined consideration of theory, experimental data, and engineering judgment. In some instances the theoretical values have been adjusted several hundred percent upward to match the available experimental results. They are reliable tools without which the so-called 'Design by Analysis' approach would have been impractical. Unfortunately many designers have misapplied the data presented, thus resulting in inconsistent designs. This article describes the data available in these two bulletins and explains the nature of inconsistency incurred in some designs. A supplemental formula is then developed for calculating the combined maximum stress intensity to be used in designs. 4 refs.

**085006 DERIVATION OF THE STRESSES IN A PRESSURIZED PIPE OR CYLINDRICAL VESSEL WITH INITIAL GEOMETRIC IMPERFECTIONS.** Several analytical methods are outlined to deal with the title problem when the vessel is free of external constraints. In essence these correspond to the Haigh equation, which provides a nonlinear relationship between the induced circumferential stress and the applied internal pressure. To make use of these analyses a survey of the cross sectional profile is required. The approach using an internal swinging arm has been found most useful. The extent to which an improved Haigh equation is valid is examined with reference to the pneumatic loading of a twin saddle supported horizontal vessel which contains imperfections and restraints at the supports. (Author abstract) 10 refs.

**085007 NONHYDROSTATIC STRESS IN FIXED-PRESSURE VESSELS AT LOW TEMPERATURES.** The anisotropic stresses are determined that can be produced in specimens located in hydrostatic-pressure vessels with a kerosene-oil or pentane-oil medium with cooling to the liquid-helium temperature. For specimens situated crosswise to the vessel channel, the compressive stress reaches 60-70 MPa for a pressure of 0.1-0.2 GPa and then is unchanged with pressure. The compressive stress is lower by one order of magnitude for similar but shorter specimens and practically nonexistent for specimens situated along the channel. (Author abstract) 9 refs.

**085008 EFFECTS OF STRESS RELIEF ON THE PROPERTIES OF C AND C-Mn PRESSURE-VESSEL PLATE STEELS.** The effect of post-weld heat-treatment on the mechanical properties of C and C-Mn pressure-vessel plate steels is presented in this work. To take account of the possible ranges of times, temperatures, heating and cooling rates, a time-temperature parameter has been used. It is concluded that reduction of as much as 10 percent of U.T.S. and Y.S. and 30°C increase of Charpy impact transition temperature for a typical post-weld heat treatment have been observed. (Author abstract) 5 refs.

Shaikh, Nazimuddin (Mehran Univ of Engineering & Technology, Jamshoro, Pak). *Mehran Univ Res J Eng Technol* v 7 n 1 Jan 1988 p 25-28.

**085009 EFFECT OF IMPERFECT CONTACT BETWEEN ADJACENT LAYERS ON THE INTEGRITY OF WRAPPED VESSELS.** Multilayer vessels are the designer's solution to the inefficiency involved in operating monoblock vessels at pressures above 50 MPa. Multilayer wrapped vessels are commonly employed in high-pressure applications of up to 550 MPa. They are advantageous to monoblock cylindrical construction in several aspects, one of which is the prestressing of the layers in order to more efficiently distribute the stresses developed due to the inside pressure. Calculation of prestress in each layer, due to shrinkage of the weld, has been reported before. Nearly all such reports are based on the assumption that layers are in perfect contact with one another. In practice, however, occasions may arise, where due to imperfect rolling and/or variations in the thickness of a plate, there remains an isolated local gap between adjacent layers. In this investigation, the size of a gap is defined in terms of its circumferential arc length and maximum radial height. (Edited author abstract). 9 refs.

## Structural Analysis

**085010 STRESS ANALYSIS OF RECTANGULAR PRESSURE VESSELS HAVING THIN-WALLED REINFORCING MEMBERS.** A modified formula is presented for rectangular pressure vessels having thin-walled reinforcing members. The formula is derived from the compatibility that relates to shear deformation of the corner. Experimental results on full-size vessels are reported. The results obtained from the authors' formula are compared with those obtained from the ASME Code and by the finite element method, which indicate that the modified formula gives better accuracy. (Author abstract) 9 refs.

**085012 LINEAR VERSUS NON-LINEAR ANALYSIS OF IMPERFECT SPHERICAL PRESSURE VESSELS.** A pressurized thin spherical shell with deviations in shape is analyzed using a geometrically linear and a non-linear version of a finite element formulation. A local geometric imperfection, described as a cosine function, is assumed, and the influence of different parameters on the

non-linear behavior is considered. The results show the importance of the non-linear terms in the analysis of slender shells, and that a linear analysis can be highly conservative, depending on the geometric parameters which define the problem. (Edited author abstract). 10 refs.

## Structural Design

**085013 CAST IRON FOR PRESTRESSED HIGH PRESSURE VESSELS.** Tests were run on assembly design of a physical model of a high pressure vessel and its components or innards, inner cavity diameter 400 mm and height 750 mm, designed to take 35 MPa (350 atmospheres) pressure. Dimensions of model and testing characteristics were selected with account taken of experience in testing similar prestressed reinforced concrete models. Predicted breaking load was 60 MPa (600 atmospheres). A basic prerequisite for successful design of prestressed reinforced concrete high pressure vessels is inadmissibility of any cracks appearing on the inner surface of the vessel, which means absence of any tensile stresses. In the case of a prestressed pressure vessel assembled from cast iron elements, this constraint is retained in full force, so that the design is arrived at on a basis of recognizing inadmissibility of any butt joints opening up, i.e., again no tensile stresses on the inner surface of the pressure vessel. 3 refs.

**085014 ADVANCES IN DESIGN AND ANALYSIS IN PRESSURE VESSEL TECHNOLOGY (PRESENTED AT THE WINTER ANNUAL MEETING OF THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS).** This conference proceedings contains eleven papers covering various facets of fracture mechanics, plasticity, and microcomputer application to structural design analysis. Part 1 of this publication contains six papers covering a range of recent developments on fracture mechanics and plasticity in pressure vessel technology. Part 2 deals with recent advances in microcomputer application to engineering design analysis. In just one decade microcomputers have emerged as a major engineering tool having proliferated to the extent where most engineers have access to one, if not their own personal machine. Software developers have taken advantage of this popular mode of computing and have written both specific purpose and general purpose of software to serve the needs of engineers in the pressure vessel and piping industry. This publication provides an overview of some of this software with the specific purpose of encouraging its use and development. Technical and professional papers from this conference are indexed and abstracted with the conference code no. 10850 in the Ei Engineering Meetings (TM) database produced by Engineering Information, Inc.

## Surfaces

**085015 J-INTEGRAL AND STRESSES AT AN INNER SURFACE FLAW IN A PRESSURE VESSEL.** This paper presents the results of elastic-plastic finite element analyses of a pressurized cylinder containing an inner surface flaw under three different load boundary conditions. The applicability of the Newman-Raju formula for calculating the stress intensity factor is extended to the calculation of the elastic-plastic J-integral up to the collapse pressure of the structure. The stress results are compared with a corresponding analysis of a compact specimen of the same material showing that the stress state

in the latter is a more severe one and, hence, will yield conservative estimates for crack initiation of the surface flaw. The phenomenon of the 'canoe' shape which has been examined for stable crack growth of surface flaws is discussed on the background of the triaxiality of the stress state. (Edited author abstract) 27 refs.

**085016 BEWERTUNG VON BERTSTVERSUCHEN NACH KONZEPTEN DER BRUCHMECHANIK UND DES PLASTISCHEN VERSAGENS.** [Evaluation of Burst Tests on the Basis of Fracture-Mechanics and Plastic-Failure Concepts]. In pressure vessels with artificial surface cracks of various sizes failure at ambient temperature and  $-20^{\circ}\text{C}$  was due to ductile fracture. The fracture surface exhibits dimples without cleavage. The onset of crack extension and instability occurred in the elastoplastic regime. When applying the fracture toughness  $K_{IC}$  in accordance with the equations of linear elastic fracture mechanics (LEFM) the stresses at the onset of crack extension derived from the potential drop measurements will, on average, be overestimated by 12%, even with a 7% correction according to Irwin. The onset of crack extension may also be determined by using the two-criteria approach and the failure assessment diagram. The failure assessment diagram and an EPRI (Electric Power Research Institute) approach assuming surface cracks to be of infinite lengths clearly underestimate the stresses to failure by 31% and 51%, respectively. Quirk's method was applied at the same time that the fracture mechanics approaches were used and was transferred to surface cracks by equating the crack surface areas or the failure stresses (according to LEFM and plastic collapse) respectively. With this, the prediction of the failure stress, being, on average, 9% or 2%, is slightly conservative. (Edited author abstract) In German. 17 refs.

**085017 PREVENTION OF CATASTROPHIC FAILURE OF PRESSURE VESSELS AND PIPING: RESULTS OF PRESSURE TEST WITH A LARGE VESSEL (HCI-TEST).** Within the Nordic countries a four-year research program in the area of elastoplastic fracture mechanics was initiated in 1985. This program aims to assess the leak-before-break (LBB) criterion for pressure vessels and piping. The major experimental effort of the program is the pressurization until rupture of large pressure vessels having dimensions resembling those of a nuclear reactor pressure vessel. The vessels tested had been in operation for 20 years in a Finnish oil refinery plant. Artificial flaws were made on the inner walls of the vessels. The flaw dimensions were defined by calculations so that the LBB condition was not anticipated during the tests. The first pressure test was performed at  $+60^{\circ}\text{C}$ , which was the lowest acceptable temperature for the hydrotest. The instrumentation used in the test included strain gauges on the inner and outer vessel walls, crack opening displacement measurement with clip gauges, potential drop measurements and acoustic emission tests. **085021 HIT ON TARGET.** The partitioning of complex surface mount printed circuit boards into more easily manageable sub-assemblies is the basic feature of the Hierarchical Interconnection Technology (HIT) system. Partitioning and connectors are discussed.

Buckley, David. *Electron Prod (London)* v 16 n 11 Nov-Dec 1987 p 12-13, 15.

**085022 DISPENSING WITH SCREEN PRINTING.** Screen printing has become an accepted methodology for low to medium volume assemblers of surface mount boards, since it enables the adhesive or the solder cream to be applied to the PCB in one step. But simple though it might be in concept, when it comes down to applying materials with viscosities ranging to 500,000 centipoise, as is the case with many solder creams, there are problems. Modern dispensing equipment offers advantages over screen printing when applying such materials as solder creams and adhesives.

Turner, C.C. *Electron Prod (London)* v 16 n 11 Nov-Dec 1987 p 27, 29.

**085023 PRINTED CIRCUITS BECOME COMPONENTS.** In this article past, present, and future of printed circuit technology are told by the editor of Printed Circuits Handbook. The main topics are the second generation, the present generation, and technology evolution.

Coombs, Clyde F. Jr. (Hewlett Packard, Santa Clara, CA, USA). *Electron Packag Prod* v 28 n 1 Jan 1988 p 64-65.

**085024 TESTER WRINGS OUT BOARDS BY FAKING FINAL SYSTEM.** Ironman automatic testers are introduced that include a capability called System Emulation Testing (SET) that addresses the problem of functionally testing extra-complex printed-circuit boards which are accessible only from their edge connectors. The SET environment replicates the board's intended operating system. That is, a board plugged into a SET tester sees no difference between the tester and its final system when it comes to interfacing and data exchange.

McLeod, Jonah. *Electronics* v 61 n 1 Jan 7 1988 p 115-116.

**085025 SURVEY OF PWB TRACE ROUTING TECHNOLOGIES - PART 1.** This is the first part of a three-part article discussing automatic PWB routing techniques and algorithm implementation. This part addresses various router types. Among them heuristic routers, line probe routers and maze routers.

Anastasi, Robert (Cadnetix Corp, Boulder, CO, USA). *Electronics* v 33 n 12 Aug 1987 p 21-23.

**085026 RELIABILITY, THERMAL AND THERMO-MECHANICAL CHARACTERISTICS OF POLYMER-ON-METAL MULTILAYER BOARDS.** Wiring requirements and thermomechanical factors related to the design and fabrication of Polymer-on-metal constraining core PWBs are discussed. The necessity of small plated-through-holes for high-density surface mount design is shown. Typical MLB constructions are shown with techniques for increasing wiring density. A design methodology for the POM construction is defined. The thermomechanical properties of copper-Invar-copper and the interactions of the MLB are described. The reliability of small PTHs is measured over a wide range of module constructions. (Edited author abstract) 13 refs.

Gray, F. (Texas Instruments Inc, Austin, TX, USA); Elkins, M. *Circuit World* v 14 n 3 Mar 1988 p 12-21.

**085027 APPLICATIONS OF POLYMER THICK FILM INKS IN SURFACE MOUNT TECHNOLOGY.** The properties and constituents of PTF inks are outlined. Surface resistivity in relation to PTF inks is defined. Applications of PTF inks are discussed with emphasis on potential design and cost benefits for SMT applications, including crossovers, polymer multilayer, printing through holes, printed resistors, carbon key pads, moulded and three-dimensional circuits. (Author abstract) 8 refs.

Fearn, D.J. (Coates Electrographics Ltd, Midsomer Norton, Engl). *Circuit World* v 14 n 3 Mar 1988 p 27-30.

**085028 CURE ANALYSIS OF PRINTED WIRING BOARDS CONTAINING REACTIVE ADHESIVE LAYERS.** This paper presents a method for analyzing the cure of multilayer circuit boards containing chemically reactive adhesive interlayers. The cure kinetics of the adhesive are first quantified by differential scanning calorimetry, using the method of Freeman and Carroll to obtain the numerical kinetic parameters. These parameters are then used in a finite-element model of the circuit board which solves the heat and species transfer equations simultaneously. It is then possible to predict the temperature and extent of reaction at any time and position within the laminate, enabling the curing program to be optimized. (Author abstract) 19 refs.

Fullerton, Rhonda (MIT, Cambridge, MA, USA); Roylance, David; Allred, Ronald; Acton, Adra. *Polym Eng Sci* v 28 n 6 Mar 1988 p 372-376.

**085029 DISPENSING VERSUS SCREEN PRINTING.** Responding to a recent article which advocated dispensing as the better method of applying solder cream to SM boards, the author takes issue with many of the

previous author's claims. In particular, he challenges assumptions about printing problems caused by the viscosity of solder cream.

Hobby, Alan (DEK Printing Machines Ltd, Weymouth, Engl). *Electron Prod (London)* v 17 n 4 Apr 1988 p 29.

**085030 ALIGNMENT-LIMITED YIELD.** As the drive to smaller linewidths, more layers and larger board areas continues, PWB makers must find better ways to understand and quantify their processes. This greater complexity has led to a marked decrease in both innerlayer and final PWB yield. The result is a much more expensive final product. The fall in yield can be attributed to both random defects and alignment-related causes. Borrowing from the semiconductor industry, the authors present a model for quantifying these alignment effects and their contribution to final yield. They show how several imaging approaches affect yield. Direct imaging, which minimizes lithography steps, posts the highest yields with shrinkage line widths. 4 refs.

Allison, Robert W. Jr. (R.A. Services); De Mott, Richard W.; Shaw, M. Alex; Powell, Michael W. *Circuits Manuf* v 28 n 3 Mar 1988 p 49.

**085031 FINE SOLDER PRINTS.** Standard solder deposition during the past decade has been at 50-mil pitch. However, 25-mil and finer pitched screen printing is becoming increasingly common as the newer fine-pitch components become more available and affordable. Fine-pitch printing puts greater demands on materials and screen printers. And current materials, rather than equipment, place practical limits on printing fineness. Today's fine-pitch solder deposition demands that screen printer operators achieve an optimum balance between the materials used in printing and the setup parameters on the screen printer. The author discusses pads tinning, screen printer flexibility and automatic alignment.

Freeman, Gary (MPM Corp, Medfield, MA, USA). *Circuits Manuf* v 28 n 3 Mar 1988 p 59.

**085032 CERAMIC-ORGANIC BRIDGE.** The author reports on a process which is designed to close the gap between ceramic and plastic printed circuit boards and in known as multilayer hybrid (MLH). He describes current and proposed techniques undertaken by a number of manufacturers.

Murray, Jerry (Circuits Manufacturing, San Francisco, CA, USA). *Circuits Manuf* v 28 n 7 Jul 1988 p 30-33.

**085033 PROFILES IN REWORK.** Rapid increases in component size, population density, and board size and thickness have recently outpaced rework station technology. To address the rework needs of SMT on both large and small boards, for large and small devices, requires process repeatability through precise control of all process parameters. These are temperature, time, heat transfer rate through control of air flow and distance to the device, and heating configuration (for uniformity). It is also necessary to establish individual time temperature profiles for each part on each board to be reworked by using an accurate temperature feedback device, such as a probe, so that results may be duplicated. Finally, and especially with massive boards, a rework system should offer optimization of a temperature ramp/soak profile to overcome a board's heat sink characteristics so that a part may be reworked without board damage.

Martel, Michael L. (Conceptronic, Gonic, NH, USA). *Circuits Manuf* v 28 n 7 Jul 1988 p 47, 49-50.

**085034 SURFACE MOUNT PCBS-MAKERS MEET USERS.** The author reports on the topics discussed at a joint SMART Group/PCA seminar on surface mount PCBs. He covers essential requirements for surface mount CAD systems; specifications; materials and finishes; registration and tolerance; and communication between manufacturer and specifier. (Edited author abstract).

Garnett, Chris. *Electron Prod (London)* v 17 n 6 Jun 1988 p 59.

**085035 PROCEEDINGS OF THE TECHNICAL PROGRAM - NEPCON WEST '87: NATIONAL ELECTRONIC PACKAGING AND PRODUCTION CONFERENCE.** This conference contains 108 papers five of which are in abstract form only. They deal with a wide variety of developments in the field of printed wiring board technology. Among the areas covered are: Surface mount technology; Productivity increase; High performance interconnect technology; Static management issues; Polymer tack films; 'JUST IN TIME' DESIGN Reflow Soldering; Total quality control; Automated assembly; Solder joint inspection; Printed wiring assembly cleaning; and Failure mechanisms and modeling. Technical and professional papers from this conference are indexed and abstracted with the conference code no. 10918 in the Ei Engineering Meeting (TM) database produced by Engineering Information, Inc.

## Accident Prevention

**085036 CYANIDES IN PLATING SOLUTIONS.** In all plating shops, including those in the printed circuit industry, solutions containing cyanide are commonplace. Because of their special properties, they are found not only in plating solutions, particularly gold plating solutions, but also in cyanide cleaners. Cyanides are known poisons and are subject to mandatory governmental regulations. Because they are known by the public, it is essential to keep supplies locked up and only available for issue by responsible personnel. Similarly, and because they are also valuable, gold cyanide solutions should be kept under lock and key: it is often necessary to protect the gold solutions by placing a thief proof cage over the plating tank when it is not in use. Toxic hazards of cyanides are discussed, along with treatment of a casualty from hydrogen cyanide gas.

Tucker, Eric. *Electron Prod (London)* v 15 n 11 Nov-Dec 1986 p 15, 17.

## Adhesion See Also ADHESIVES—Selection.

**085037 FROZEN ADHESIVE ADVANTAGES IN ELECTRONIC MANUFACTURING.** This paper describes a relatively new methodology which helps eliminate the problem of utilizing the wrong epoxies, silicones, polysulfides, or polyurethanes, and their accompanying catalysts and additives, for specific applications. It also offers the advantage of providing a cleaner operation, consistent formulation, and a reduction of waste that is an inevitable by-product of self-mixing ingredients. It involves the pre-blending of resins and hardeners in a laboratory, having them packaged in appropriately marked containers, freezing them, and then storing them in a freezer at -40°F. Once out of the freezer, the compound is ready for use in a minute or two. By tracking the effectiveness of a given frozen compound, chemists are able to recommend modifications where the performance or handling characteristics have not met expectations. The degree of control obtained through frozen mixtures assures consistency that takes out the guesswork and possible messiness of mixing at the work station.

Rocheleau, Hal (Poly-Freeze Inc, Van Nuys, CA, USA). *Electron Manuf* v 34 n 7 Jul 1988 p 18-19.

**085038 AN OVERVIEW OF ADHESIVES USED IN ELECTRONIC MANUFACTURING.** This paper presents a description of the various types of adhesives often used in electronic applications. These types include cyanoacrylates, anaerobics, acrylics, urethanes, silicones, epoxies, hot melts, solvent cements and ultraviolet curing systems. Application systems are also discussed.

Lilly, Ron (Loctite Corp, Newington, CT, USA). *Electron Manuf* v 34 n 7 Jul 1988 p 23-25.

## Analysis

**085039 HOW TOLERABLE ARE BOARD TOLERANCES?** The effect of line widths and dielectric thicknesses of printed circuit boards (PCB) on their electric properties are considered. The control of physical tolerances is discussed, with special attention to the controlled impedance, critical tolerances, structural effects, etchout and burial depth. 5 refs.

Moosmann, Karl (Electri-onics, Libertyville, IL, USA); Bartos, Sara. *Electronics* v 33 n 3 Feb 1987 p 25-26.

**085043 CFM SOLVES A WORST CASE.** Manufacturing mixed-technology assemblies (surface mount and through-hole components) efficiently in the flexible environment of a contract manufacturer is a challenge. To produce high volumes of mixed-technology assemblies and stay flexible, a continuous flow manufacturing (CFM) method is used. CFM reduces waste and increases quality by continuously monitoring all elements of operation. Products are processed one unit at a time. This differs from common manufacturing procedures where products are handled in batches. Three requirements for achieving CFM are given: in-process controls, preventive maintenance and process verification. Each is necessary to efficiently produce a quality product.

Arnold, Dan (EMD Associates Inc, Winona, MN, USA). *Circuits Manuf* v 28 n 1 Jan 1988 p 61-62.

**085044 ROBOTIC WORKCELLS FOR PCB ASSEMBLY.** Light assembly robots have been successfully used in printed circuit board assembly for several years now. Having grown in sophistication during this time, they perform an increased share of the total work required to successfully assemble PCBs. A modern robotic assem-

bly system is a fully integrated workcell, providing manufacturers with a flexible and dependable tool for producing quality products.

Schnedler, Dave (Intellex Inc, Corvallis, OR, USA). *Electron Packag Prod* v 27 n 2 Feb 1987 p 108-110.

**085045 FLEXIBILITY, SPC LOOM LARGE IN CAPTIVE SMT ASSEMBLY.** Two leading manufacturers have each establish consolidated surface-mounting operations to make varied products for their different business units. This article discusses how Allen-Bradley partitioned SMT assembly into four lines and how John Fluke Manufacturing Co. linked SMT processes within on flexible line.

Pound, Ronald (Electronic Packaging & Production, Newton, MA, USA). *Electron Packag Prod* v 28 n 1 Jan 1988 p 42-45.

**085046 SMT AND JIT: THE DYNAMIC DUO.** The installation of a modular assembly line based on surface mount technology (SMT) is considered to increase production, yet reduce production floor space. The manufacturing is changed to a just-in-time (JIT) manufacturing system along with a zero-defect attitude. While not yet in full operation, this system is already slashing costs and maximizing product quality.

Metcalfe, Henry (Foxboro Co, Foxboro, MA, USA); Jacques, Joe. *Circuits Manuf* v 27 n 12 Dec 1987 p 67, 69-71.

**085047 TURN THE KEY AND GO?** Turnkey production lines for the assembly of single mount technology (SMT) components on printed circuit boards (PCB) are considered. Buying an SMT line from a single source appeals to companies with a limited engineering staff—small- to medium-sized firms making everything from fish finders to wiring devices to push-button units for door entry. Some well-known makers in the computer industry have taken this route as well. Wang Laboratories and Control Data Corp. have recently installed single-sourced SMT lines.

Tuck, John (Circuits Manufacturing, San Francisco, CA, USA). *Circuits Manuf* v 28 n 2 Feb 1988 p 67-68, 70, 72.

**085048 ORGANISING HIGH DENSITY PCB ASSEMBLY.** Techniques used in the assembly of high density printed circuit boards (PCB) are considered that are used with surface mount (SM) and conventional components. The surface mount technology (SMT) enables the necessary density to be achieved, with conventional components being used where lack of availability or other reasons have precluded the use of SM components. The soldering of surface mount devices (SMD) on the board is also described.

Upton, Roger (Radamec Microsystems Ltd, Crowthorne, Engl). *Electron Prod (London)* v 17 n 2 Feb 1988 p 22-23.

**Automatic Testing** See Also ELECTRONICS ENGINEERING—Computer Aided Engineering.

**085049 HOW TO USE PWB FAULT PREVENTION TO IMPROVE MANUFACTURING YIELDS.** Printed wiring board manufacturers traditionally have used automatic test equipment (ATE) for detecting board faults. In an attempt to be as efficient as possible, they used testing as a screening device to prevent defective products from leaving the factory and moving into subsequent production steps. Many manufacturers have introduced the bare board testing step into their fabrication processes. This paper discusses several reasons for the growing acceptance of bare board testing. Other subjects include: testing parameters, defect prevention testing and cost considerations.

**085050 PRUEFSTRATEGIE UND WIRTSCHAFTLICHKEIT BEIM AUTOMATISCHEN LEITERPLATTENTEST.** [Testing Strategy and Cost Effective-

ness with Automatic Testing of PC Boards]. The economical production of reliable electronic flat subassemblies requires an adapted and individual testing strategy. This article presents various test conceptions and explains the essential factors of determination. (Author abstract) In German.

Erfurth, Michael. *F&M Feinwerktech Messtech* v 95 n 5 Jul-Aug 1987 p 325-328.

**085051 USING COMPUTER AIDED TESTING FOR PRINTED WIRING BOARD APPLICATIONS.** Faced with new and more stringent PWB design requirements, automatic test equipment (ATE) manufacturers are striving to meet the objective of supplying solutions to problems while keeping costs within reach. The need for affordable, flexible, reliable equipment is accentuated by the trends toward use of surface mount devices, application specific integrated circuits (ASIC) and very large scale integration (VLSI). This paper discusses the subjects of time and cost saving in PWB production, custom-designed equipment and flexibility of test equipment. Improving communication is one way that ATE manufacturers are trying to keep pace with changing PWB test needs, and to integrate testing into the total manufacturing process.

O'Loughlin, Michael (Electri-onics, Libertyville, IL, USA); Bartos, Sara. *Electronics* v 33 n 3 Feb 1987 p 39-42.

**085052 FAST SOLUTION TO INTERMITTENT FAILURES.** The GenRad Functional and Stress Testing (GR FaST) System is a comprehensive diagnostic environment which combines the functional electrical testing commonly used at military repair depots with the vibration stress screening used during the design and production cycle by suppliers of advanced electronic equipment. By testing boards for electrical functioning while they are subjected to the simulated stress of their real-world operating environment, the system identifies not only hard failures but also those intermittent flaws which normally escape detection in the quiescent state. In essence, it provides military repair depots with test methods which are equal to the complexity of the products being tested.

Grafton, William (GenRad Inc, Milpitas, CA, USA); Wagner, Robert. *Eval Eng* v 27 n 1 Jan 1988 6p between p 36 and 45.

**085053 AUTOMATISCHER ABGLEICH BEIM LEITERPLATTENTEST.** [Automatic Adjustment Associated with Testing of Printed Circuit Boards]. Advantages of automatic adjustment are enumerated. These include: high precision and accuracy; simpler service so that less quantification is necessary; shorter training period; and computer aids that are applicable for complex and frequently changing tasks. The incorporated trimming screws and control equipment are based on the Robotrim system. In German.

Muehlbauer, H. *Elektron Prod Prueftech* n 9 Oct 1987 p 18, 23-24.

**085054 SECOND-GENERATION PCB SELF-LEARN.** Manufacturing defect analysers generally incorporate some form of self-learn capability, allowing board tests to be developed in as short a time as possible without the need for skilled programmers. Existing methods generally meet these two objectives but lack both fault coverage and component level diagnostics. Following a brief introduction to the use of manufacturing defect analysers, this paper describes a new self-learn technique which allows a board test to be generated incorporating individual tests on each component. This provides diagnostics close to those of manually developed programs. (Author abstract)

Matheson, Robert (Marconi Instruments Ltd). *Comput Aided Eng J* v 4 n 5 Oct 1987 p 209-212.

**085055 BARE-BOARD ATE/EMBEDDED COMPONENT TEST. FIRST THINGS FIRST.** Embedded components, multilayers and several thousand pads have forced production managers to demand that all boards be tested prior to placing the first component on them.

Guidelines are providing for buying bare-board testers which are available in a variety of styles and sizes for just about any board configuration. The problems particular to boards with embedded components are discussed.

Anon. *Eval Eng* v 27 n 3 Mar 1988 p 40, 42, 45.

**085056 FUNCTIONAL BOARD TEST HYBRID DIAGNOSTICS. THE EVOLUTION AND ADVENT OF ANALOG SIGNATURE ANALYSIS.** The concept and application of signature analysis are discussed. The various techniques involved in network verification. There are two modes of digital network verification and six modes of analog network verification. However, any of the analog network verification modes can be applied to a period square wave function.

Reiss, Alan (Schlumberger ATE, Latham, NY, USA). *Eval Eng* v 27 n 3 Mar 1988 p 106-107.

**085057 TOWARDS A NEW APPROACH TO FAULT LOCATION ON PCBs.** There is an urgent need to provide a more integrated and effective approach to the test requirements of board manufacturers. There is a widespread acceptance in the ATE industry, which has traditionally produced sophisticated test hardware, of the need for research into the application of scientific techniques to fault diagnosis. This need has resulted in a joint research program, known as Project FLAIR, between Factron Schlumberger and the Department of Electrical Engineering, Imperial College. The technical aim of the research is the development of diagnostic algorithms which locate faults on electronic printed circuit boards.

Rae, Bill (Imperial Coll). *New Electron* v 20 n 16 Aug 11 1987 p 20, 22.

**085058 USING IN-CIRCUIT ATE FOR DEPOT REPAIRS.** NCR's Worldwide Service Parts Center (WSPC) has been using in-circuit ATE to test and repair field failures for more than three years. The repair process is a fast and economic approach in repairing defective PC boards. In-circuit ATE can be a very effective standalone depot repair test system with test comprehension levels in excess of 95 percent. Every test program is verified by repairing and system-testing a minimum of 50 defective PC boards. When at least 95 percent of the repaired PC boards pass the system test, the program is made available to repair field returns. After the program is verified, the system test no longer is required.

Christopher, J.R. (NCR Corp, Peachtree City, GA, USA); Quattlebaum, Edward W. *Eval Eng* v 27 n 8 Aug 1988 p 136-139.

**085059 SYSTEM FOR PCB AUTOMATED INSPECTION USING FLUORESCENT LIGHT.** Research was performed on the detection of faults such as shorts, cuts, and nicks in a printed circuit board pattern. The possibility was investigated of detecting a pattern by illuminating a printed circuit board with violet or ultraviolet rays and detecting the pattern using the (yellow or other) fluorescent light emitted by the base material consisting of glass-epoxy or glass-polyimide, etc. It was found that the pattern could be detected clearly by selecting an optical fiber that would separate the emitted fluorescent light from the illumination and using a detector consisting of a high-sensitivity TV camera that produces a silhouette image in which the base material is bright and the pattern is dark. A printed-circuit-board pattern inspector using this approach was developed. Test operation of the inspector in a plant demonstrated that it performs consistently good pattern inspections. 9 refs.

## Bonding

**085061 PALIDELIGHEDSUNDERSOGELSE AF TAB-TEKNOLOGIEN. UDFORT I SAMARBEJDE MED A/S MODULEX OG GN DANAVOX A/S.** [Tape Automated Bondings]. The present report is a reliability investigation of five Tape Automated bonded variants and two wirebonded variants. Four TAB-variants were delivered from A/S MODULEX, and one TAB-variant and one TAB-film wirebonded variant were delivered from GN DANAVOX A/S. All variants were visually inspected, electrically tested (as a 'go/no go test'), and the terminals were pull-tested before and after some environmental exposures as humidity, dry heat, industrial atmosphere, salt mist, vibration, and acceleration. The results of the investigation showed that none of the variants failed during and after the environmental exposure, and that the weakest part of the TABN-variants were the terminals, which easily could be damaged during mounting and handling. In Danish. 9 refs.

## Classification See BAR CODES: BAR CODES—Design.

## Cleaning See Also ELECTRON DEVICE MANUFACTURE.

**085064 SMT FLUX CLEANING.** Complete removal of harmful flux residues under SMCs is hindered by the difficulty in forcing solvent through extremely narrow clearances between components and the board, and by the inability of current nondestructive testing methods to detect remaining residues. Long immersion times, liquid sprays directed at the liquid surface of the cleaning bath and/or ultrasonic agitation are the methods commonly used to promote penetration of solvents. The studies reported here evaluated the effectiveness of spraying high-pressure fluorosolvent directly onto the com-

ponent/board interface. 5 refs.

Lermond, David S. (DuPont, Wilmington, DE, USA). *Circuits Manuf* v 27 n 9 Sep 1987 4p between p 86 and 92.

**085065 EXAMINATION OF SOLVENT CLEANING FOR PRINTED WIRING BOARD APPLICATIONS.** Performance factors for efficient cleaning of through hole, surface mount, and mixed technology printed wiring board assemblies are similar in nature. Surface mount assemblies require solvents with the highest possible solvency and may require revised cleaning techniques and equipment. Flux type, soldering techniques, solvent blend, cleaning equipment, and cleaning cycle are other factors which must be considered to achieve proper assembly cleaning. Improper board assembly cleaning leaves harmful flux residues consisting of both ionic and organic (non-ionic) flux components. Ionic levels can be characterized by present test methods. However, quantitative methods only recently have been introduced for determining levels of organic (rosin) residues. This paper discusses various factors to consider when selecting a solvent cleaner including solvent temperature, substrate wetting solvency and constant boiling blends. Safety considerations are also discussed.

Archer, Wesley L. (Dow Chemical Co, Midland, MI, USA). *Electronics* v 33 n 7 May 1987 p 11-14.

**085066 ASSESSMENT OF SOLVENT CLEANING PERFORMANCE AND SAFETY.** When choosing a cleaning material and method, through hole assemblers should select one that is compatible with the construction materials of both the components and printed wiring board (PWB), it is important that the cleaning process not leave residues that are cosmetically unacceptable, or that interfere with proper conformal coating adhesion or automatic test equipment. The performance index provides a method of generating a two or three digit number that characterizes a flux/solder/deflux system. For through hole technology, moderate pressure (30-50 psig) vapor/spray, inline, fluorosolvent defluxers are efficient and capable of meeting basic requirements for reliability after soldering and cleaning. Compared to through hole, surface mount (SMT) and mixed technology have performance factors that are more complex and subtle, which affect the choice of a cleaning agent and method. The paper discusses advantages and trade-offs of solvent cleaners, evaluating solvent safety and management liability for PWB manufacturers.

**085067 PLASMA-DESMEARING VON MULTI-LAYER-LEITERPLATTEN.** [Plasma Desmearing of Multilayer Printed Circuit Boards]. The significance attributed to the cleaning of multilayer printed circuit boards is illustrated by the number of publications on this subject. This article reports on the present state of development of plasma desmearing etchback plants, on some aspects to be taken into account with rigid-flexible circuits, and contains some remarks on the removal of hydrogen fluoride and ozone from the waste gases. (Edited author abstract) In German. 4 refs.

Kegel, Bert; Naversnik, Rudolf. *Metalloberflaeche* v 41 n 11 Nov 1987 p 521-525.

**085068 MODERNE ASPEKTE ZUR LOCHWANDREINIGUNG MIT PERMANGANATHALTIGEN LOESUNGEN.** [Cleaning Punched-Hole Walls with Permanganate-Containing Solutions]. Since 1965, the year in which industrial production of multilayer circuits supposedly started, it has been necessary to look for a smear removal process which would be technically efficient, advantageous from the processing engineering viewpoint and economically justified. It was decided therefore, to switch over to an alkaline permanganate-containing medium, since this was the only way to avoid wicking and the red-ringing phenomenon. (Edited author abstract) In German. 3 refs.

Ehrich, Hans-Juergen. *Metalloberflaeche* v 41 n 11 Nov

1987 p 531-536.

**085069 EVALUATION OF PWB CLEANING ISSUES - PART 2.** This is the second part of a two-part article about issues in PWB cleaning. Part two covers PWB cleaning safety and environmental concerns. (Edited author abstract)

Clark, Jerry (Gram Corp, Hancock, NH, USA). *Electronics* v 33 n 9 Jun 1987 p 38.

**085070 SPECIFICATION GUIDE FOR AQUEOUS AND SOLVENT PCB CLEANING CHEMICALS AND EQUIPMENT.** In Electronic Manufacturing's specification guide for aqueous and solvent PCB cleaning chemicals and equipment, contributing companies have listed solvents aqueous detergents, equipment, and accessories used for cleaning printed circuit boards. These include hydrocarbons, chlorinated hydrocarbons, fluorinated or fluorinated chlorinated, and azeotropic types, as well as saponifiers. It also includes automated, semi-automated, solvent, and aqueous equipment. Details are provided for each chemical section. Various types of equipment are listed, along with a variety of accessories.

Anon. *Electron Manuf* v 34 n 3 Mar 1988 p 12-15, 18-23.

**085071 RESTRICTIONS ON THE USE OF CHLOROFLUOROCARBONS FOR CLEANING SOLDERED PCBs.** The flux residues on almost all soldered printed circuit boards are removed using the chlorofluorocarbon (CFC) 113. In just one year's time production of this solvent will almost certainly be curtailed, on a scale agreed internationally. This is a major issue that needs to be addressed by the electronics assembly industry worldwide. This paper presents (i) the background that has led to the restrictions being placed on production and consumption of solvent 113, (ii) the international agreement and timetable for the implementation of the restrictions and (iii) the perceived opportunities that are available to the industry to meet this challenge. (Edited author abstract). 27 Refs.

Lea, C. (NPL, Teddington, Engl). *Circuit World* v 14 n 4 Jul 1988 p 4-12.

**085072 CLEANING ALTERNATIVES FOR THE 1990S.** In August 1987, the EPA held a conference in Washington DC with consultants and users from the electronics industry to determine the feasibility of practical cleaning alternatives to reduce emissions of chlorofluorocarbon solvents which are considered to be a major contributor to the ozone problem in the stratosphere the world over. This paper presents a resume of these goals and how they will affect cleaning in the electronics industry. Electronic design and packaging are the first steps in the soldering and cleaning. Selection of components compatible with alternative cleaning methods as well as process changes to permit low solids fluxes in some cases where cleaning can be eliminated are discussed. 'High containment' in-line solvent cleaning systems which reduce emissions are likely to become the new standard for the industry. Machines will become longer in order to include internal drying stages, instead of allowing a board with residual solvent trapped under components to evaporate after it leaves the machine prior to electronic test. Alternative solvents will become available. Designers of components and assemblies will respect their designs to permit water cleaning, even for surface mount assemblies. (Edited author abstract). 14 Refs.

Elliott, D.A. (Electrovert Ltd, Laprairie, Que, Can). *Circuit World* v 14 n 4 Jul 1988 p 44-48.

**085073 DESIGN CONSIDERATIONS TO FACILITATE EASE OF CLEANING PRINTED WIRING ASSEMBLIES.** There are many factors to consider when designing a printed wiring assembly to facilitate ease of cleaning, some of which have been briefly addressed in this article. They include choice of solder process, device termination, board complexity, space considerations and use of adhesives. But the major fact is the need for a team

approach to design and produce an economically manufacturable and testable board or assembly. Achieving this means that boards and assemblies can be cleaned with little or no problem at all.

Kenyon, W.G. (DuPont, Wilmington, DE, USA). *Electron Manuf* v 34 n 8 Aug 1988 p 26-28.

## Coatings

**085074 CONFORMAL COATINGS SEAL OUT ADVERSE ENVIRONMENTS.** Conformal coatings are liquid resin formulations used in protecting assembled printed circuit boards from the environment. Being initially liquid, they conform to the topography of the board and components, then cure to provide a thin, protective film. Depending upon the coating application process, number of coats applied and the type of resin used, the film thickness can range from less than one mil on up to 20 mils or more. Greater thicknesses approach the realm of potting, thereby defeating the purpose of a conformal coating - which is to provide protection from the environment without excessive resin shrinkage and component stress, offer repairability and minimize the weight penalty.

Markstein, Howard W. (Electronic Packaging & Production, Newton, MA, USA). *Electron Packag Prod* v 27 n 3 Mar 1987 p 82-84.

**085075 CONSIDERATIONS FOR SELECTING, APPLYING PWB CONFORMAL COATINGS.** The use of conformal coatings in electronics has grown out of the need to improve device performance and to protect devices from environmental conditions that may cause premature failure. Failure may be caused by moisture, contamination, and fungus growth. To show how different requirements influence the final decision, three common applications are examined. The first is a high volume, lower cost consumer-oriented circuit card assembly that needs protection from elements encountered in every day use. The second example focuses on devices used in industrial applications. There are more demanding applications, such as protecting assemblies that have to meet stringent military and aerospace industry requirements. Parylene is mentioned as particularly attractive coating in most of these applications.

Stewart, Jeffrey (Para Tech Coating Co, Laguna Hills, CA, USA). *Electronics* v 33 n 12 Aug 1987 p 11-12.

**085076 SMART CARDS YIELD HIGH MEMORY CAPACITIES FOR MASS-STORAGE AND DATA-SECURITY USES.** Thanks to advances in IC fabrication and packaging technologies, you can now obtain high-capacity memories or complete  $\mu$ P-driven systems in credit-card-sized packages. These memory cassettes, or so-called smart cards (they really do not have any intelligence), suit an extremely wide variety of applications, ranging from the customization of terminals and other peripherals, to data logging, and to mass storage for computers that must run in hostile environments. The cards also have varying memory capacities.

Terry, Chris (EDN, Newton, MA, USA). *EDN* v 32 n 20 Oct 1 1987 p 61, 63-64, 67.

**085077 ELECTROMECHANICAL RELAYS FIND A NICHE ON THE CIRCUIT BOARD.** Tiny new electromechanical relays may be a better choice than solid-state components for some straightforward switching jobs. Solid-state switches have entirely replaced relays in logic circuitry. But for straightforward switching tasks, relays cost less and often do the job better. Manufacturers, moreover, have cut relay size and improved reliability. Electromechanical relays also have become widely avail-

able in PCB-mount packages that are suitable for automated soldering. (Edited author abstract)

Carlisle, Ben H. (Machine Design, Cleveland, OH, USA). *Mach Des* v 59 n 18 Aug 6 1987 p 64-68.

**085078 FINISH FIRST.** In the elimination of solder joint defects in surface mounted technology (SMT) opinions differ about the merits of solder-dipped finishes versus electro-plated finishes. Proponents of solder dipping content that electroplated finishes are porous, allowing oxidation of the base metal that can lead to dewetting during the solder process. Modern, automated plating systems have overcome these problems by exerting excellent control over process parameters. Fine-grain finishes low in codeposited organics with very low thickness variability from lead to lead and unit to unit are now possible with electroplated leads. 10 refs.

## Computer Aided Analysis

**085081 INTEGRATED ANALYSIS FOR PCBs.** The author reports on an integrated electrical and mechanical design system to perform a full range of mechanical analysis techniques on printed circuit boards. The system automatically generates a solid model from printed circuit board (PCB) layout data. Because mechanical properties are included in component libraries, the design model can be used without modification for solid, surface, and wire frame modeling as well as for drafting.

Barton, Brian (CAD/CAM, Ann Arbor, MI, USA). *CAE Comput Aided Eng* v 7 n 5 May 1988 p 78, 80.

**Computer Aided Design** See Also COMPUTER AIDED ENGINEERING; COMPUTER SOFTWARE—Quality Assurance; INTEGRATED CIRCUIT MANUFACTURE—Computer Applications; INTEGRATED CIRCUITS—Computer Aided Design.

**085082 CHECK LIST HELPS YOU CHOOSE A PC-BOARD AUTOROUTER.** An automatic printed circuit (PC) board-routing program can save a lot of time, provided that it is used as a design aid and it is not expected to solve all routing problems. Before you can choose the right pc-board autorouter for your needs, you need to understand how these programs work and how their features affect your project's entire design cycle. This article explains the functions of eight types of autorouters and provides a check list of 26 key features that will help you compare and select routers.

Roth, John (Aptos Systems Corp). *EDN* v 32 n 18 Sep

3 1987 p 191-196, 198.

**085083 MAJOR ROLE FOR PCs IN PCB DESIGN.** Many recent PC hardware performance improvements, taken in conjunction with a number of developments that will affect application software costs, will result in personal computers playing a more significant role in PCB CAD and may very well take market share away from engineering workstations. The article discusses the capabilities of available personal computers applied for printed circuit board design.

Marsh, H.G. (CAD Software). *New Electron* v 20 n 15 Jul 21 1987 p 29-31.

**085084 PHOTOPLOTTERS: CREATING THE CRITICAL SHADOWS.** This article addresses many of the questions facing those who must evaluate, recommend or purchase photoplotting systems. Several of the basic issues leading up to the decision to buy a photoplotting system are discussed. These issues have changed considerably in the past several years, as both plotting technologies and PWB design rules have evolved. A comparison matrix, showing the published specifications of most of the photoplotters on the market as of this writing are presented.

Henningsgard, Robert C. *Printed Circuit Des* v 4 n 9 Sep 1987 p 8-15.

**085085 CONSIDERATIONS FOR CHOOSING AN IN-HOUSE PHOTOPLOTTER.** Taking the process of board design and production to its next logical step, the newer issue of the decade has become that of affordable photoplotting. The photoplotter, once a gigantic, complicated, slow, and expensive piece of equipment, has finally evolved to become a small, simple-to-use, fast, low cost solution for service bureaus and end users, some of which are discussed.

Peddie, Cynthia. *Printed Circuit Des* v 4 n 9 Sep 1987 p 17-21.

**085086 LASER PHOTOPLOTTING TECHNOLOGY.** This article gives some of the basic facts about laser photoplotters. We review the different technologies that are available and explain the positive and negative characteristics of each. We explore the problem of determining which solution best meets your needs. We do this by providing several key criteria that can help you decide what is best for your organization.

Hill, Jerry. *Printed Circuit Des* v 4 n 9 Sep 1987 p 22-23.

**085087 PLOT YOUR ARTWORK WITHOUT PHOTOPLOTTING.** The original intent of photoplotters was to meet the needs for producing errorless and accurate 1:1 artwork for intricate IC masks. The resulting equipment is overkill for most densities of hybrid and PCB designs. If a company has a need for all kinds of circuits and densities, then a photoplotter can certainly meet all their artwork demands. If a company is more limited as to the circuits it produces, then a photoplotter may be a larger bite than that company should have to chew. This article provides an alternative for those companies who need the advantages of CAD but cannot justify purchasing a photoplotter.

Langley, Bill. *Printed Circuit Des* v 4 n 9 Sep 1987 p 24 and 32.

**085088 DESIGNING ON THE MAC.** Two software products for the Macintosh personal computer are reported. Both of these packages are for the same purpose: to enable the user to draw printed circuit boards on a Mac screen, and to take the resulting output file and: print it out, to ImageWriter (dot matrix) printer, LaserWriter (laser printer 300 dots per inch), or LinoType machine (1200 dots per inch) (LinoTypes are to be found at the new desktop publishing places that have appeared lately

around the Mac). Laser printer or LinoType quality is probably adequate for PCB photo artwork. Some operational details are included.

Lizard, A. *Printed Circuit Des* v 4 n 9 Sep 1987 p 33-36.

**085089 PCB ARTWORK FROM A PLOTTER.** The author works for a company that manufactures high density surface mount RF PC boards which are incorporated into their product. They were faced with the problem of our CAD system not being able to easily handle this type of PCB and so switched over to an Apple Macintosh computer with a PCB layout software package. They found it necessary to overcome the obstacles present in pen plotting PCB artwork, because they had an early release of the software that would not output to a photoplotter. Some of the problems that can be encountered and how they can be rectified are explained.

Newman, Glenn P. *Printed Circuit Des* v 4 n 9 Sep 1987 p 40, 42.

**085090 CAD CONSIDERATIONS FOR SMT BOARDS.** The general steps for using a CAD system to design SMT boards are basically the same as designing regular multilayer PCBs. We should be aware, however, of the similarities and differences which relate to designing both through hole and SMT PCBs. The first-time user of CAD for the design of an SMT board can be intimidated by the visibility issues relating to seeing both sides on the board at the same time. Automatic tools can go a long way toward minimizing errors but only if the basic system has SMT capabilities first.

Nedbal, Richard A. *Printed Circuit Des* v 4 n 10 Oct 1987 p 10, 14-16, 18.

**085091 SMT MANUAL DESIGN SYSTEM.** The SMT artwork design system is well suited for multilayer as well as double-sided boards. Using the specially designed 30 lines/inch grid along with a pin registration bar and pre-punched polyester film, the designer is assured of achieving accurate registration of all layers. Symbols such as sequential reference designators, targets, board delineation marks, etc., in addition to precision slit tape and any required through hole DIP patterns, can be used to complete the artwork.

Kem, Fred H. *Printed Circuit Des* v 4 n 10 Oct 1987 p 31-34, 36.

**085092 CONSIDERATIONS FOR SELECTING COMPUTER AIDED DESIGN SYSTEMS FOR PRINTED WIRING BOARDS.** As the speed, density, and overall complexity of printed wiring boards increase, so does the time required for their design. In a marketplace that demands prompt delivery, inefficiency and delays cannot be tolerated. Computer aided design (CAD) hardware and software manufacturers have introduced and modified products to accommodate both complex designs and changing requirements for efficiency and prompt turnaround. The paper discusses many factors which must be considered when selecting CAD hardware (also called a platform) and/or software.

Bartos, Sara (Electronics, Libertyville, IL, USA); O'Loughlin, Michael. *Electronics* v 33 n 3 Feb 1987 p 19-22.

**085093 CONTOUR PROGRAM SMOOTHES 'STRIP' DISCONTINUITIES.** Discontinuities in microstrip transmission lines result in actual circuit operating parameters that are different from the theoretically designed values. Exact design of these discontinuities - either the step- or open-end types - requires the correct discontinuity equivalent circuit. Designers often use only one of the two discontinuity equivalent circuit components - the capacitive or the inductive component. However, a software-based technique ensures use of the correct equivalent circuit. This technique also reduces circuit complexity, provides more reliable circuits, and generates printed-circuit artwork. The technique is applicable to discontinuity steps of any size and is easily incorporated into existing circuit artwork plotting facilities. 11 refs.

Hutchings, J.L. (CSIR, Pretoria, S Afr); Nortier, J.R.; Lambert, D.A.T. *Microwaves RF* v 26 n 12 Nov 1987 p 129-130, 132-134, 138-139.

**085094 DESIGNER'S LOOK AT AUTOROUTING.** About seven years ago in the engineering lab, it was decided that About seven years ago in the engineering lab, it was decided that the only way to layout the next generation of large (8 inch  $\times$  10 inch), high density (1.0 sq. inch per IC) printed circuit boards (PCBs) was to use a CAD system with an automatic router. A list of some of the requirements the router must be capable of is presented.

Anon. *Printed Circuit Des* v 4 n 11 Nov 1987 p 15-18.

**085095 CAD FOR PC DESIGN: A SOFTWARE SURVEY.** Comments are presented which accompanied a table of answers to 150 questions by 30 suppliers of PCB software. All suppliers reviewed the table in June 1987. This covers virtually all of the low cost layout packages and some of the popular higher cost systems. The comments also document experiences of 50+ users of PCB CAD in the Pacific Northwest. The software grouping is: IBM compatible only, AutoCAD add-on, workstation, Atari and Amiga, Macintosh, then schematic capture.

Lahore, Henry. *Printed Circuit Des* v 4 n 11 Nov 1987 p 19-23.

**085096 RELATIONSHIP BETWEEN DESIGN RULES AND ROUTABILITY.** The successful use of automatic routers requires a firm grasp of the mathematics of router algorithms. An attempt is made to re-examine some of the basic rules of layout as they apply to the use of automatic tools for board routing.

Tasker, Shiv; Wines, Lisa. *Printed Circuit Des* v 4 n 11 Nov 1987 p 30, 34-37.

**085097 SELECTION CRITERIA FOR SURFACE MOUNT DESIGN SYSTEMS - PART 1.** Although surface mounting is not a new technology, it is one that has presented new and unusual problems. As surface mount technology evolved, many problems occurred because people tried to design surface mount on systems that were never intended for it. The article centers on the limitations of traditional systems and human interface with the design system.

Arana, Phil (Calma Co, Milpitas, CA, USA). *Surf Mount Technol* v 1 n 3 Jun 1987 p 22-23.

**085098 EINFACHE ERMITTLUNG VON SUBSTRATDATEN IM GHz-BEREICH.** [Simple Determination of Substrate Data in the GHz Region]. A method is described which makes it possible to determine in a simple manner the substrate data of materials for printed circuit boards in the GHz region. For this purpose use is made of the hf CAD program 'Supercompact'. It is thus possible to realize cost effectiveness of the P/C-board material. In German. 4 refs.

Dirks, Christian. *Elektronik* v 36 n 19 Sep 18 1987 p 149-152.

**085099 EXTENDED LAYERING ALGORITHM FOR MULTILAYER PRINTED WIRING BOARDS.** Layering problem of multilayer printed wiring boards in the single-row routing approach is considered. For use in high density printed wiring boards, an extended layering algorithm is proposed for the case of street capacity  $K > 2$ , while all conventional algorithms are for  $K = 2$ . (Author abstract) 5 refs.

Ghameshlu, Mohsen (Hiroshima Univ, Higashi-Hiroshima, Jpn); Yoshida, Noriyoshi. *Trans Inst Electron Inf Commun Eng Sect E (Engl)* v E70 n 10 Oct 1987 p 906-908.

**085100 DESIGNING CIRCUITS WITH PCs.** Laying out a printed circuit board (PCB) is a perfect application for a computer. Dedicated PCB workstations have performed the task for some time. A few years ago, personal

computer (PC) software vendors began offering CAD packages. The early CAD packages helped the design process but had many deficiencies. The number of components and circuit layers they could work with was fairly limited. And few of the early packages offered autorouting of the circuit traces. Today, packages are available that can handle up to 1,000 components, and most offer autorouting. Though the circuit completion rate for these routers is still less than that of a workstation, it is high enough - typically around 90% - to drastically reduce the designers task. The author describes the printed circuit CAD packages.

Bahniuk, Douglas (Machine Design, Cleveland, OH, USA). *Mach Des* v 59 n 18 Aug 6 1987 p 91-95.

**085101 SOLVING THE INSOLUBLE: PCB PLACEMENT.** The article focusses on the complexity of the placement problem, describes the placement tools within the Board Station PCB Layout system and demonstrates how advanced design automation techniques can be applied to assist and complement the effort of the pcb designer. The authors seek to set the foundation for the artificial intelligence approach in solving the placement problem.

Kohkani, Kanti; Rogoyski, Eric; Chou, Anna; Lin, Juno. *Electron Prod Des* v 8 n 4 Apr 1987 p 53-56.

**085102 MULTILEVEL ELECTRONIC DESIGN ENVIRONMENTS.** The article reviews the place of printed board design systems in the larger networks which are now being configured. A new analog simulation package, SABER, which is outlined, offers better convergence and performance improvements of 10-15 times in comparison to SPICE. The advantage of NFS in a distributed CAE/CAB/CAM environment is stressed.

Turner, Nigel. *Electron Prod Des* v 8 n 4 Apr 1987 p 59-61.

**085103 PCB DESIGN - IMPLICATIONS FOR MANUFACTURING.** The paper centers on the implications of PCB CAD for manufacturing. The author argues that the design quality and integrity are as important to manufacturing as they are to engineering. In order to customize links to special process equipment, manufacturing needs to have access to all design data and system outputs.

Farrant, David. *Electron Prod Des* v 8 n 4 Apr 1987 p 65-66.

**085104 EXPANDING CAPABILITIES IN 'BUDGET' CAD.** The article traces the progress in developing PC CAD systems. A number of software products are outlined, including EE Designer and Executive CAD, which run on an IBM AT, XT or compatible PC. The difficulties in selecting the most cost-effective system from those offered by today's market are mentioned.

Hewer, Johnathon. *Electron Prod Des* v 8 n 4 Apr 1987 p 83-84.

**085105 PWB DESIGN AND THE CADDS DESIGNER.** The intent of this article is to give the reader some insight into some of the processes involved with the fabrication of PWBs, along with some helpful design tips, and to stress the importance of being able to incorporate this knowledge into the design of their boards. Some problems associated with computer-aided design/drafting systems (CADDS) are discussed.

DeSantis, John A. *Printed Circuit Des* v 5 n 1 Jan 1988 p 16-21.

**085106 CHANGING OF PCB CAD.** The demarcation between logic design and PCB design was once clearly defined by the technology available to perform each task. Logic design, even of complex boards, was accomplished with colored pencils and paper, while physical board design used large mainframe computers. Computational power was more easily applied to the tangible design than

the abstract. It is argued that integration of board design tasks into CAE tools will redefine the nature of the board designer's job.

Smith, Lee D. *Printed Circuit Des* v 5 n 1 Jan 1988 p 22, 26-27, 29.

**085107 COMPUTER-AIDED DESIGN ANALYSIS TO IMPROVE PCB RELIABILITY.** Various types of circuit element adjacencies in a high density printed circuit board are described. A methodology for using CAD tools to analyze printed circuits and enumerate the circuit adjacencies is outlined. Two examples are cited where utilizing the methodology induced the technology engineer to make design changes that increased the product reliability with no loss in circuit performance. 3 refs.

Shaul, Roy F.; Haining, Frank W. *Printed Circuit Des* v 5 n 1 Jan 1988 p 30, 32-34, 38.

**085108 CALAY AIMS TO USE CAD DATA TO BUILD AND LOAD BOARDS.** The use of computer-aided design (CAD) data in the computer-aided manufacturing (CAM) workstations of printed circuit (PC) boards is presented. The ECAM (Electronic Computer-Aided Manufacturing) work station is presented, a system that takes a giant step toward full automation. ECAM brings single-keystroke commands to the CAM world; it expands the repertoire of translators that convert CAD data for use in pc-board manufacturing, include translators that convert CAD data for use in board stuffing. The ECAM system provides 'neutral' data-base conversion, that is, it can quickly convert design data into equipment-specific file formats. For example, a manufacturing engineer might create a file for an n/c drill machine that breaks down halfway through a run. With a few keystrokes, he can create a new file for an entirely different machine and resume the production run. On other systems, he would have had to manually change the file over to the new n/c machine.

McLeod, Jonah (Electronics, New York, NY, USA). *Electronics* v 60 n 22 Oct 29 1987 p 61-63.

**085109 DEVELOPING A PRINTED CIRCUIT BOARD DESIGN SYSTEM.** In 1982 Hewlett-Packard addressed the computer-aided printed circuit board layout problem with HP EGS (HP's Engineering Graphics System), a product that provides design capture (via an electrical schematic) and general physical design capabilities. In 1986 HP introduced its first fully automated printed circuit board layout product as a member of the HP DesignCenter family. This HP Printed Circuit Design System (HP PCDS) is a fully functional computer-aided design application that couples printed circuit board layout to electrical engineering design, manufacturing, and testing. This article provides an overview of the product and the environment in which it runs, and includes a discussion of HP PCDS' Design Module. 1 ref.

Regelson, Elaine C. *Hewlett Packard J* v 39 n 1 Feb 1988 p 65-67.

**085110 AUTOMATING THE PRINTED CIRCUIT BOARD DESIGN PROCESS.** The author describes the placement method used in the HP Printed Circuit Design System (HP PCDS). He then discusses placement improvement methods. He finally describes the autorouter, its parameters and its method of operation. 1 ref.

Jackoway, Gary. *Hewlett Packard J* v 39 n 1 Feb 1988 p 68-71.

**085111 MANAGING HP PCDS WITH THE DESIGN SYSTEM MANAGER.** A description is given of the Design System Management (DSM) part of the HP Printed Circuit Design System. The discussion covers: design history and version control; DSM architecture; DSM networks; file structure; interface; design access; file security; the spooler system; and customization and usability.

Reese, Paul S.; Mayotte, Mark E. *Hewlett Packard J* v 39 n 1 Feb 1988 p 71-76.

**085112 MULTIDEVICE SPOOLER FOR TECHNICAL APPLICATIONS.** The HP Printed Circuit Design System (HP PCDS) produces output that goes to a wide variety of physical devices. The DSM (Design System Manager) spooler system provides a method for accessing each of the peripherals and the Autorouter Module through a common user interface. This lets HP PCDS users concentrate on designing printed circuit boards instead of interacting with each device individually. The DSM spooler can be easily customized. This allows customer sites to configure the systems to that it works with their peripherals and manufacturing processes. Because the spooler is integrated within DSM, the user does not need to specify information that is already known by DSM, such as the names and locations of files. In addition, DSM can be used to transfer job files and status information across the network.

Lienhart, Deborah H. *Hewlett Packard J* v 39 n 1 Feb 1988 p 77-80.

**085113 INTEGRATING APPLICATIONS IN A DESIGN MANAGEMENT SYSTEM.** The author describes the Design System Manager, which was developed in conjunction with the HP Printed Circuit Design System (HP PCDS) to allow an organization to control the access to and the distribution of their CAD data. The basic functions of a design manager are to provide the file management tasks of versioning, access control, archival storage, and reporting. The discussion focuses on the environment initialization, automatic execution, and the DSM query facility.

Mayotte, Mark E. *Hewlett Packard J* v 39 n 1 Feb 1988 p 80-83.

**085114 IPC-D-350: ONE STANDARD FOR PC DESIGN.** Over the years, IPC members have spent a great deal of effort in the development of a printed board standard language. The IPC-D-350, 'Printed Board Description in Numeric Form,' was initially released in 1972, approved for use by the U.S. Department of Defense (required by MIL-STD-275) and continues today to be a viable language. In addition, the D-350 computer format for boards was supplemented in 1985 with companion languages for drawings (IPC-D-351) and electronic data base descriptions (IPC-D-352). Both of these standards were also adopted by the DoD. Work is now in progress for library descriptions and test vectors.

Bergman, Dieter. *Printed Circuit Des* v 4 n 12 Dec 1987 p 17-18.

**085115 USING EDIF FOR PCB DESIGN.** The Electronic Design Interchange Format (EDIF) is emerging as the most advanced means of exchanging design data between CAE system vendors. EDIF can describe many different aspects of an electronic system, including netlists, schematics, PCB layout, IC layout, simulation, and documentation. The EDIF standard is new and evolving. Its use in the printed circuit board industry is still experimental. This article describes some of the open issues that must be resolved in order to allow the commercial use of EDIF for PCB design and layout. It will help you to set realistic expectations and schedules as you plan for changes in your CAE/CAD systems.

Clawson, Harvey. *Printed Circuit Des* v 4 n 12 Dec 1987 8p between p 19 and 32.

**085116 REAL-WORLD CONSTRAINTS ON PRINTED CIRCUIT CAD PERFORMANCE.** The design rules imposed on PCB auto-routers and placement programs reflect the state of manufacturing process capabilities of PCB fabrication and assembly operations. They can often be very restrictive, as can the tough layout design rules arising from the need to manage transmission-line behavior in high-speed circuits. 2 refs.

Keeler, Robert (Electronic Packaging & Production, Newton, MA, USA). *Electron Packag Prod* v 27 n 2 Feb 1987 p 88-90.

**085117 EFFECTS OF INTEGRATED CAE/CAD ON THE DESIGN CYCLE.** This article explain how and

why the PCB designer's day-to-day activities will change due to integrated CAE/CAD, and discusses general CAE concepts pertinent to the PCB designer using an integrated CAE/CAD system.

Munich, Steve. *Printed Circuit Des* v 5 n 2 Feb 1988 p 9-12, 15-18, 22-23.

**085118 AUTOPLACEMENT: THE LONELIEST SOFTWARE IN TOWN.** From an engineering and design standpoint most autoplacement software does not work well. The problems are complex. One autoplacement program cannot possibly incorporate the intricate engineering and design criteria for all PCB applications. Digital, analog, SMT, ECL, TAB, and two-sided component placement are a few of the challenges. Autoplacement advancements are driven by the knowledgeable consumer. It is argued that the evaluation of and emphasis on competent placement will demonstrate which CAD vendors are dedicated to the advancement of PCB design tools.

Rygiel, James. *Printed Circuit Des* v 5 n 3 Mar 1988 p 5-6, 10-12.

**085119 OVERVIEW OF PLACEMENT ALGORITHMS.** While printed circuit board routing appears to be more difficult, it is a complete placement algorithm that continues to evade CAD developers. Commercial 100% routers are commonplace, but placement still requires manual intervention. In many cases a board may be completely placed by a designer. Due to this fact, the selection and use of a proper placement tool can save many man-hours of design. Placement algorithms can be divided into two sub-classes by their usage. Constructive placement algorithms start from an empty or partially placed board and produce a placed arrangement. Iterative improvement algorithms are those which begin with a placement and optimize its arrangement according to some cost function. An attempt is made to examine cost functions.

Meyers, Ben; Elmer, Diane. *Printed Circuit Des* v 5 n 3 Mar 1988 p 13-14, 16.

**085120 PROS AND CONS OF AUTOMATIC COMPONENT PLACEMENT.** Many electronic design automation (EDA) systems available today provide automatic placement tools. These tools, although readily available on most platforms and in all price ranges, are seldom or never used by engineers or designers. Automatic placement tools often do not meet the user's expectation, so the tools are left idle while the designer places the components either manually or interactively. The placement problem is discussed, and guidelines for eliminating the problem are indicated.

Bracha, Gabriel; Harvel, Jerry; Dvir, Assaf. *Printed Circuit Des* v 5 n 3 Mar 1988 p 17-20.

**085121 BRIDGING THE GAP: PRODUCT DESIGN GROUPS VS. COMPUTER-AIDED DESIGN.** The design of printed wiring boards and flex harnesses for electronic, electromechanical, and electrooptical systems is of prime importance to Martin Marietta. Most of our products - missiles, projectiles and communications systems - contain active electronic equipment that is unique in its application and which must be packaged on printed wiring boards and interconnected with flex or rigid-flex harnesses with specific form factors. The author reports the gradual development of modern technology, starting with the 1960's. Presently used methods are described.

McEachnie, William E. *Printed Circuit Des* v 5 n 3 Mar 1988 8p between p 23 and 35.

**085122 LAYOUT INCLUDING PARASITICS FOR PRINTED CIRCUIT BOARDS.** An automatic layout system is developed for optimal simultaneous placement of elements and equipotential nodes and routing interconnection paths that can be applied to multilayer analogue printed circuit boards (PCBs) including parasitic couplings. The objective is to minimize the influence of

parasitic capacitance and inductance couplings of printed paths on performance of analogue circuits as an electrical criterion. A force model has been used to determine optimal placement where the sensitivities of network function on parasitic capacitances and inductances are the sets of weighted coefficients between forces of attractions and repulsions. The routing algorithm is a combination of topographic simulation method with minimum length connection path. Placement and routing algorithms have been developed, programmed and compared with conventional force algorithm and the Lee algorithm. Practical results of frequency characteristics of printed circuit boards of a wide-band HF amplifier have been obtained and presented. (Edited author abstract) 14 refs.

Wawryn, Krzysztof (Technical Univ of Koszalin, Koszalin, Pol). *Int J Circuit Theory Appl* v 16 n 2 Apr 1988 p 107-128.

**085123 CAD REVIEW: APTOS SYSTEMS.** In a previous issue, a checklist for comparing CAD systems and software was printed within these pages. That guide, adapted from a publication created by Aptos Systems (Scotts Valley, CA), raised questions that should be asked when evaluating any PC-based CAD system. From the comments of Printed Circuit Design's readership, a standardized questionnaire evolved that is to be used for future reviews of CAD bundled systems or software packages. These reviews should allow quick, consistent and unbiased comparisons regardless of the review date. This initial review is directed toward Aptos. Aptos Systems offers designers two paths from conception to artwork-ready design. One path is Rgraph, Aptos' front-to-back schematic capture and board layout system. A less expensive path is provided by Aptos' Criterion I and Criterion II.

Balingit, Bill. *Printed Circuit Des* v 5 n 4 Apr 1988 p 23-26, 30-33.

**085124 IGES: TRANSFERRING DESIGN DATA.** One exchange format for transfers from any CAD system to any other make of CAD system is called IGES. Initial Graphics Exchange Specification. Product Data Exchange Specification refers to a current project, which is also known as PDES. Sometimes IGES refers to a document and sometimes to the organization (now more correctly called IGES/PDES) of people who created and maintain that document. This article focuses on IGES, with brief mentions of three other exchange vehicles.

O'Connell, Larry. *Printed Circuit Des* v 5 n 4 Apr 1988 p 34-36, 40-42, 44.

**085125 BLIND BURIED VIAS.** A three-dimensional computer-aided design (CAD) capability permits the blind buried via (BBV) application in the production of surface mount technology (SMT) printed circuit boards (PCB) in order to obtain compact interconnects. The CAD system auto-routes to terminal pads, interconnects selected layers, and generally looks at a board as the three-dimensional thing that it is. A new data structure handles components on both the top and bottom of the board, auto-routes around vias, and brings a layer to a surface for making contact.

Murray, Jerry (Circuits Manufacturing, San Francisco, CA, USA). *Circuits Manuf* v 28 n 4 Apr 1988 p 62-64.

**085126 CASE STUDY: REDESIGN WITH A PERSONAL COMPUTER.** The use of personal computers in printed circuit design is considered. Experience with the PC is reported. A unique redesign problem is discussed, along with computer graphics aid component placement. The importance of cost effectiveness is pointed out.

Bange, Brian D. (Precision Printed Circuit, Houston, TX, USA). *Printed Circuit Des* v 5 n 5 May 1988 p 36-39.

**085127 DESIGNER'S VIEWPOINT.** Current design and layout techniques associated with printed-circuit boards are discussed. It is being argued that the fact that we have abandoned the central CPU approach for the workstation is the best thing that could have happened.

Jodoin, Claude J. (United Technologies Automotive Group, Dearborn, MI, USA). *Printed Circuit Des* v 5 n 5 May 1988 p 41-42.

**085128 DESIGN OF A ROBOTIC WORKSTATION FOR COMPONENT INSERTION.** The characteristics of electronics manufacture have changed: instead of high volumes of the same product, the trend is toward much smaller volumes of many varieties of similar products. In this environment, the ideal assembly machine would be capable of virtually limitless adaptability. Using robotic technology, AT&T at Merrimack Valley has undertaken a project to design such a machine for printed-wiring-board assembly. This paper describes the configuration of the resulting workstation for component insertion on the automated in-line manufacturing system. (Author abstract) 1 ref.

Decelle, Linda S. (AT&T Merrimack Valley Works, North Andover, MA, USA). *AT&T Tech J* v 67 n 2 Mar-Apr 1988 p 15-22.

**085129 COMMON DESIGN ERRORS DECREASE MULTILAYER YIELDS.** A list of common design errors likely to compound the fabrication challenge is drawn up. This list provides a set of guidelines to pass on, in capsule form, to internal or external customers. And that, in turn, may help to achieve the goal of truly fabrication-driven design.

Nap, Kimbel A. (Automated Systems Inc, Brookfield, WI, USA). *Electron Manuf* v 34 n 5 May 1988 p 10-12.

**085130 OVERVIEW OF TRENDS IN COMPUTER AIDED DESIGN.** For the last five years, some of the biggest CAD breakthroughs have taken place in the area of PCB routing. The introduction of special purpose accelerators made significant reduction in routing time about two to ten times faster. Accelerators, because they were so fast, permitted designers to tweak their designs and make them more manufacturable - fewer vias, fewer layers, etc. They also permitted true multilayer routing of large dense boards. User interface has become important to the value of a CAD system. Other trends include changes in library creation, automation of PCB component placement and application of artificial intelligence.

Anastasi, Robert (Cadnetix Corp, Boulder, CO, USA). *Electron Manuf* v 34 n 3 Mar 1988 p 26-28.

**085131 PC CAD SOFTWARE GAINING ON WORKSTATION PROGRAMS.** An interesting shift in the computer-aided-design (CAD) market will be seen in 1988 as more engineers buy software that runs on personal computers (PCs). Lower priced PC software products will be able to do what more expensive workstation software traditionally accomplished, and cost differences will no longer be justified. The paper describes four areas of new product opportunity in the CAD arena: concept design, design verification, manufacturing tools and PCB layout area.

Collison, Rick (Personal CAD Systems Inc, San Jose, CA, USA). *Electron Manuf* v 34 n 3 Mar 1988 p 29-30.

**085132 CHOOSING A MONITOR FOR PC-BASED CAD/CAE.** Resolution is at the top of the list of criteria for choosing monitors. Other features PCB designers should look for are the highest levels of brightness, contrast, and bandwidth rate.

Gonor, Kevin L. (Monitronix Corp, Westerville, OH, USA). *Electron Manuf* v 34 n 3 Mar 1988 p 31-32.

**085133 USING A CAD/CAE SYSTEM FOR FLEXIBLE CIRCUIT DESIGN.** While working on an internal productivity project geared to develop computer aided flexible circuit design capabilities, a breakthrough in project management, project design communication, design documentation, and automated flexible circuit design and fabrication emerged. These capabilities have been realized by taking the basic hierarchical design structure of a certain CAD/CAE schematic capture system and expanding it beyond the scope for which it was originally intended.

Lacy, Steve (Power, Distribution & Telemetry Systems Design, Pomona, CA, USA). *Electron Manuf* v 34 n 3 Mar 1988 p 35-36.

**085134 TECHNIK UND ABLAUF BEI CAE/CAD-LEITERPLATTENENTWICKLUNGEN.** [Engineering and Procedure in CAE/CAD Printed-Circuit Board Developments]. The computer-assisted development of PCBs displays functional and constructional design phases. Systematic use of CAE/CAD design systems results in time savings as well as production documentation of greater precision. Several variations exist for employing computer processes, their effective application being conditional on a smooth cooperation between user and manufacturer. (Author abstract) In German. 6 refs.

Ammon, P.; Guth, F. *F&M Feinwerktech Messtech* v 96 n 5 May 1988 p 215-219.

**085135 HIDDEN DOLLARS IN YOUR COST.** With CAD data being available with artwork films, PWB manufacturers can make PWBs faster, better and cheaper. CAD data allows reduced tooling and production costs. PWB quality improves with better matching of tooling to the manufacturer's process. Tooling preparation requires fewer steps, with these steps being automated, and thus takes less time and shortens delivery lead time. Independent PWB manufacturers have cultivated business with PWB buyers willing to release CAD data with their film artwork. These PWB manufacturers achieve quality, yield and cost improvements that have made them better suppliers and more effective competitors. They have taken on more complex multilayer work profitably, with their cost savings paying back their investment in CAD/CAM equipment.

Juha, Mike (Excellon Photonics Div, Costa Mesa, CA, USA). *Circuits Manuf* v 28 n 3 Mar 1988 p 3.

**085136 INTERFACING WITH A SERVICE BUREAU.** An attempt is made to explain how one can provide information to the service bureau in a way that both will be able to understand what is expected of each other and the finished result will be exactly what was needed, if not better than what was expected. These steps will also enable control to be maintained while not slowing up the progress of the design. The use of CAD (computer aided design) as a design tool is considered. Economic aspects are discussed.

Umina, John (Product Development Co, Newton, MA, USA). *Printed Circuit Des* v 5 n 7 Jul 1988 p 27-33, 35.

**085137 AUTOROUTER SOFTWARE.** This article is concerned with writing automatic router software for good printed circuit board design and the practical goals which should be aimed for. PCB routing is but one facet of the design process. Schematic design, or data entry and part placement precede the problem of routing the board. If the placement has not been properly studied in order to minimize the interconnection problem, no router, human or computer, will produce a good board design. Designing good router software for experienced layout designers is not an easy task. The design of a software tool which is of practical use to a professional requires a thorough understanding of the way in which a professional layout designer manually routes a board. Some useful guidelines are presented.

Maton, John (Academi Systems, Livermore, CA, USA). *Printed Circuit Des* v 5 n 10 Oct 1988 p 27-30, 34-35.

**085138 EVALUATING PERSONAL COMPUTER AUTOROUTERS.** Features like automatic placement, gate and pin swapping, design rule checking, CAE-to-PCB integration, and surface mounted design support are now available from personal CAD vendors at total system prices ranging from 3,000 dollars to 20,000 dollars. Today's personal computer CAD tools meet the need of their users in practically every aspect of PCB design. A good autorouter can save you a lot of work and

reduce your design time by 50 percent. A bad one or one not suited to your design needs will be worthless. The right router will depend on your design requirements because different routers will be effective on different boards. This article has been written to enable a user with limited time to evaluate autorouters quickly to find one that will work well with this layout rules and design technology.

Marsh, Michael (Router Solutions, Littleton, MA, USA). *Printed Circuit Des* v 5 n 10 Oct 1988 6p.

**085139 MINIMIZATION OF THE NUMBER OF LAYERS FOR SINGLE ROW ROUTING WITH FIXED STREET CAPACITY.** A set of three algorithms is presented for solving single-row routing problems with a fixed street capacity using the least number of layers. The main difference among these algorithms is in the strategy used to search for an optimal solution, which greatly affects the performance. At the extreme points of the strategy are algorithms Q and S. The worst-case time complexity is linear for algorithm Q and exponential for algorithm S. The best-case time complexity of all the algorithms is linear. The main disadvantage of algorithm Q is that the constant associated with its time complexity bounds is large. On the other hand, the constant associated with the best-case time complexity bound for algorithm S is small. An experimental evaluation of the performance of the algorithms is presented. 9 refs.

## Computer Aided Engineering

**085141 HOW TO EVALUATE CAE EQUIPMENT FOR PWB LAYOUT - PART 1.** This is the first part of a two-part article discussing CAE equipment evaluation. Part one covers linking schematic capture to layout, and part placement. (Author abstract)

Miller, Timothy C. (Daisy Systems Corp, Mountain View, CA, USA). *Electronics* v 33 n 12 Aug 1987 p 25.

**085142 HOW TO EVALUATE CAE EQUIPMENT FOR PWB LAYOUT - PART 2.** This is the second part of a two-part article discussing CAE equipment evaluation. This part covers routing functions. (Edited author abstract)

Miller, Timothy C. (Daisy Systems Corp, Mountain View, CA, USA). *Electronics* v 33 n 14 Sep 1987 p 51.

## Computer Aided Manufacturing See Also ELECTRONICS PACKAGING—Modular Construction.

**085143 ACCURATE PLACEMENT OF SMDs: VISION MEETS THE CHALLENGE.** Assembling printed circuit boards populated with surface mount devices (SMD) is a problem manufacturing engineers have been struggling with for several years. In some cases, where the volume is high and the variety of boards is low, hard automation has provided an answer. For those producing low volumes of a broad mix of boards, robots guided by machine vision and CAD/CAM systems have proven most successful. As the number of leads on SMDs

increases and distance between the leads decreases, the problem grows in complexity, making the role of vision guidance and inspection more critical. This article describes some techniques for using vision to inspect leaded SMDs, and provides inputs to a robot for their placement on printed circuit boards. Leaded parts are more difficult to inspect and place than parts such as leadless chip carriers (LCC), but many of the same techniques apply to both.

**085144 FEATURES TO COMPARE WHEN EVALUATING PWB COMPUTER AIDED MANUFACTURING SYSTEMS.** Because the main benefit of an advanced system derived from the comprehensive array of features, these benefits can be demonstrated only in a general way by way of example. This paper discusses the following example of advanced features: scanning, design rule checking (DRC), creation of special solder masks, drill and route tape preparation, elimination of nonfunctional pads, merging of positive and negative layers, and communication interfaces.

McDonald, Roy K. (Optrotech Inc, Billerica, MA, USA). *Electronics* v 33 n 7 May 1987 p 30-32.

**085145 TAPPING CAD DATA FOR PC BOARD PANELIZATION.** A workstation 'panel editor' can bridge the CAE/CAD database to CAM and provide the ability to create manufacturable printed circuit panel artwork from one or more single copies of a PCB. The data available from the panel editor that are crucial to the various islands of automation within CAM are accessed through a data query language facility and through a host of direct machine interfaces. The panel editor places the solutions to manufacturing problems in the manufacturing environment. Manufacturers can create and modify their own panel artwork without having to rely on the CAE/CAD groups. Similarly, the database and tools for configuring and programming fabrication, assembly and test equipment are available in the workstation.

White, Lisa D. (Cadnetix Corp, Boulder, CO, USA). *Electron Packag Prod* v 27 n 3 Mar 1987 p 51-52.

**085146 OVERVIEW OF PWB PANELIZATION STATIONS, PLOTTERS.** The two main components of a CAM phototooling system are the panelization station (front end) and plotting device (output). Although many front end systems have been introduced recently, there have been few changes in plotters, which may cost between 60-70 percent of the total system. This paper stresses on selecting a phototooling system. Photoplotter should be selected based on its speed, accuracy and resolution.

Herzka, Dani (Scitex America Corp, Bedford, MA, USA). *Electron Manuf* v 33 n 18 Dec 1987 p 15-16.

**085147 PAPERLESS TRAIL TO ZERO DEFECTS.** The author reports on a paperless-rework and data collection system for surface mount technology printed circuit testing based on a manufacturing database system. The assembly area consists of two functionally identical SMT lines and one through-hole technology line connected by conveyors. Total placing capacity is 20,000 discrete/hr and 7200 ICs/hr. Running 152 hr, the factory produces 25,000 boards/week. All of the boards are single-sided mixed technology with only a small percentage of through-hole components. The boards are all for the personal computer industry and consist of disk controllers or communications boards for distribution to original equipment manufacturers (OEMs), value-added distributors (VADs) or value-added retailers (VARs). Data is collected at five stages for work-in-process (WIP) tracking and yield information purposes.

Arp, Rudy (Western Digital Corp, Irvine, CA, USA). *Circuits Manuf* v 28 n 3 Mar 1988 3p.

**085148 NEW MACHINES FOR OLD.** The implementation of a phased CIM strategy at a printed-circuit-board (PCB) manufacturing site in England is re-

ported. This site produces 95% of the company PCB's for all its product lines, and the range of boards covers over 600 types, varying from simple double-sided boards to complex multilayer boards with up to 18 logic layers. On average 10,000 assembled and tested boards are produced each week, although at peak periods this figure can rise to over 30,000 a week. The manufacturing process begins with laminate and components entering the factory, and ends with tested PCBs leaving to be fitted into products at assembly plants or stored for field spares.

Banister, Ray (ICL Mainframe Systems). *IEE Rev* v 34 n 7 Jul 14 1988 p 283-287.

**085149 KNOWLEDGE-BASED CAP SYSTEM IN PCB PRODUCTION.** The introduction of computer-aided planning in printed circuit board (PCB) production was the basis of a project designed to increase planning quality and shorten response times for new planning or for tenders. To achieve this aim, the knowledge of the methods engineer has to be modelled in an EDP system. In such cases, the result is called a knowledge-based system. Implementation is based on an interpretive decision table technique which was preferred to the more complex expert systems. Implementation of the first planning logic took 4 months and it has since been used in production with great success since April 1987. (Edited author abstract). 6 Refs.

## Computer Integrated Manufacturing See Also MATERIALS HANDLING—Computer Aided Design.

**085150 HOW ONE COMPANY IS APPROACHING JIT.** At Calcomp's Display Products Division in Hudson, N.H., a different approach produced gains just as big, with little or no capital investment. One sentence sums up what JIT means to Calcomp - 'The philosophy calls for the production of only the minimum necessary units in the smallest possible quantities at the latest possible time.' With that overall guideline, Calcomp personnel accomplished the following: a 30% reduction in floor space required; a 70% reduction in work-in-process (WIP); an increase in quality that brought preshipment audit yields from 82% up to more than 96%, and a decrease in production cycle time from 12 weeks to less than 5. That list does not even include intangibles such as higher employee morale and better rapport between manufacturing engineers and designers. Furthermore, the floor space that was opened up gave Calcomp room to expand their business to include contract manufacturing of printed circuit boards.

Krepchin, Ira P. *Mod Mater Handl* v 43 n 1 Jan 1988 p 101-104.

**085151 SOFTWARE INTEGRATION EXPEDITES ANALYSIS.** Mechanical considerations such as packaging, thermal deformation, stress and vibration can frequently be as important as electronic properties in printed circuit board design. Yet conventional CAD/CAM systems usually make such analysis intolerably expensive. In order to perform a mechanical analysis, geometric, thermal and other properties of the PCB's components must be tediously entered one by one in an environment different from the one where the PCB was originally laid out. To eliminate this problem, an electronic design system, Bravo3, offers fully integrated mechanical and electronic computer-aided engineering.

Barton, Brian (Applicon, Ann Arbor, MI, USA). *Electron Packag Prod* v 28 n 1 Jan 1988 p 87-89.

**085152 IMPLEMENTING A CIM SYSTEM FOR MULTILAYER PWB FABRICATION.** A flexible computer integrated manufacturing (CIM) system is the key to efficient management of a dynamic, custom-built printed wiring board manufacturing facility. The PWB often is the last component designed for a particular application, but usually is the first component assembled,

changed, or modified during revision. This paper describes a CIM program in place at AT&T Technology Systems' Richmond, Va. facility which permits a PWB design to be put into production in less than one day, and cuts overall lead time in half. The system is used to provide various benefits, including real-time data for sequencing jobs and setting up equipment, and monitoring output, quality, and shipping. Although the system has unique features, the approach that AT&T has taken is one that many multilayer board fabrication facilities can apply.

Sage, Donald L. (AT&T Engineering & Computer Systems Development, Berkeley Heights, NJ, USA). *Electronics* v 33 n 11 Jul 1987 p 31-33.

**085153 TEKTRONIX INTEGRATES PCB MANUFACTURING.** Designed to hold sophisticated microprocessors and other complex devices, bare circuit boards must be built to proper wiring connections and signal routing. To make things more difficult, components are moving to higher levels of integration and designers continue to pack more functions into less space. Board manufacturers are striving to keep up. Some, however, are not only keeping up but in fact have gained a significant edge through computer-integrated manufacturing. The authors describe customer benefits testing, improvements in automating manufacturing and methods for better process planning.

Christensen, Jay (Tektronix, Beaverton, OR, USA); Hill-Tanquist, Sheri. *CAE Comput Aided Eng* v 7 n 5 May 1988 p 97-98, 101.

**085154 CIM-PRAXIS IN DER LEITERPLATTEN-FERTIGUNG EINES COMPUTERHERSTELLERS.** [CIM in Practice in a Computer Maker's Printed-Circuit Board Production.]. A description is given of a computer-integrated production and quality assurance system for the assembly and inspection of the large multilayer PCBs. Equal light will be thrown on the manufacturing sequence, inspection steps, data flow and material flow. Positive experiences with the system are reflected in drastic reductions of throughput times, high changeover flexibility, improved product quality, and transparent and up-to-date data on all levels. (Author abstract). 1 Ref. In German.

**Computer Interfaces** See COMPUTERS, MICROCOMPUTER—Components.

## Computer Simulation

**085155 3-D ELECTROMAGNETIC ANALYSIS OF PRINTED BOARDS BY A NOVEL BOUNDARY ELEMENT METHOD.** Computer simulations of devices, circuits and systems are a major benefit to the electronics industry because they can remove the need for very costly design iterations in hardware. However such simulation can only be useful if it provides a sufficiently accurate prediction of the actual hardware performance. An example is the modification to the performance of a circuit implemented on a printed circuit board (PCB). This is due to the parasitic electrical behavior of the board itself. Problems that arise vary from common or differential mode coupling to crosstalk and feedback. It is therefore clear that accurate simulation of such circuits requires a mathematical model of the PCB. A unique description of the electrical behavior of the board is an  $N \times N$  admittance (or impedance) matrix, where  $N$  is the number of pads. This must be found at each frequency of interest. All the problems would be accounted for in a circuit analysis that are included this model. The broad outline of a method for finding the matrix is described here together with comparison between simulation and measurement. 5 refs.

**Construction** See SUBSTRATES—Materials.

## Contacts

**085156 OVERVIEW OF BARRIER TERMINAL STRIPS.** Barrier terminal strips are one of the most widely used devices to terminate wires because of their versatility - they are available in various top and bottom termination styles - and cost effectiveness, both initial and installed cost. The devices provide increased insulation to stop creepage and arcing, eliminate time-consuming splicing, and provide a simple and convenient method for field wiring - only a screwdriver is necessary. Usually, high density circuitry can be attained with barrier terminal strips, which saves panel or PCB space. The result is a professional-looking termination rather than a jumble of wires. Barrier terminal strips also permit convenient circuit changes made by rearranging wires, and provide a good test point for trouble-shooting. In addition, circuit tracing is simplified when strips are imprinted with circuit designations. This paper discusses the benefits of using less expensive thermoplastic terminal strips, market trends in this field and barrier strip characteristics.

Twombly, Daryl (Vernitron Corp, Laconia, NH, USA). *Electron Manuf* v 34 n 5 May 1988 p 38-41.

**085157 MACHINE DESIGNED TO CLEAN CONTACTS TO IMPROVE PCB CONNECTOR RELIABILITY.** This paper describes a contact cleaner for PCB used by a leading computer manufacturer. The company's failure rate for insertions was 47 percent; almost half of the PCBs inserted into ZIF (zero insertion force) type connectors had to be removed, cleaned, and reinserted. Moreover, the faults resulting from poor contacts were often of an intermittent nature. After including the extra step of cleaning all contacts with the contact cleaner before inserting the boards, the manufacturer reported a failure rate of less than 3 percent, a significant improvement. Among the lessons learned is that contact cleanliness cannot be determined visually. Almost microscopic particles can interfere with proper contact between the board and connector. Finger prints, masking adhesives, fatty oils, and rosin flux are readily removed by the combination of solvent and mechanical scrubbing, but none of the gold is removed and lint, formerly a problem, is eliminated.

Larrabee, Bryce B. (Harvard Products Inc, Harvard, MA, USA). *Electron Manuf* v 34 n 8 Aug 1988 p 14-15.

## Cooling

**085158 COOLING DEVICES TAKE THE HEAT FROM SMDs.** Shrinking board size has changed the rules for thermal design: A surface-mount assembly that occupies only 40% of the space of its through-hole counterpart can nevertheless dissipate as much power. Achieving adequate reliability requires that one understands and applies the new rules. Products ranging from CAD tools to heat sink help develop and implement a strategy to limit semiconductor junction temperatures to a level that delivers the desired reliability. A CAD software package is presented that allows one to impose thermal as well as electrical constraints when determining where to place components on a circuit board.

Strassberg, Dan (EDN, Newton, MA, USA). *EDN* v 32 n 25 Dec 10 1987 p 96-102, 104, 106.

**085159 TAKING THE HEAT OFF.** Because of the lack of space in tightly-packed sealed electronic assemblies used in military/aerospace equipment, the removal of unwanted heat is achieved by means of conduction cooling. Appropriately designed heat sinks, or thermal planes, transfer the heat to the 'cold wall'. But too many designers leave heat dissipation considerations until the last minute. Enco's computer-aided thermal analysis system is used to establish the thermal problems associated with each printed circuit board (PCB) assembly. Factors taken into account by the analysis include heat generated on the board, heat transferred from other boards, thermal characteristics of the enclosure system, and any convection or radiation cooling that may be

available.

**Costs** See Also COMPUTERS, MICROCOMPUTER—Performance.

**085161 PCB COST CONSIDERATIONS.** Printed circuit boards are the one common factor in all electronic assemblies. Every aspect of their design, manufacture and use has become so familiar that the purchase of PCBs seems routine. Now surface mounting raises new issues, whilst highlighting some old ones, and often the first symptom of things going astray comes with a surprise at the quotation stage; and abnormally high price. With surface mounting promising new economies this can certainly come as a shock but it either indicates over-specification in an area that was thought to be trivial or it brings to attention the true worth of some aspects of PCB capabilities that, once appreciated has acceptable value. This article compares through-hole assembly and surface mounting and examines the actual cost features of PCB.

Topham, David (Cambridge Interconnection Technology). *New Electron* v 20 n 14 Jul 7 1987 p 18-19.

## Cutting

**085162 EXAMINATION OF WATERJET CUTTING SYSTEMS FOR PWB PANEL SEPARATION.** Waterjet cutting is a method of depaneling PWB's which not only has advantages such as clean, smooth cuts, and the ability to accurately make contour cuts, but it lends itself to work with automated systems. Surface mount devices, a variety of substrates, and line automation, will contribute to a strong future for waterjet cutting in the PWB industry. Enhancements on the waterjet method include the abrasive jet system. The system uses an abrasive intensifier pump, which is a high pressure water system with inexpensive abrasives introduced into the stream. The enhancement expands the use of waterjet-type methods into cutting other materials, including glass, ceramics, and metallic substrates.

Jones, Ed (Flow Systems Inc, Kent, WA, USA). *Electronics* v 33 n 1 Jan 1987 p 23-24.

## Decontamination

**085163 FLUXES AND PCB CLEANING.** Comments are made on recent articles published on the use of 'No Clean' fluxes and on the alternative methods of cleaning PCB assemblies.

Fenner, Mike (Dage GB Ltd). *Electron Prod (London)* v 16 n 10 Oct 1987 p 53.

**085164 DETECTION OF IONIC CONTAMINATION UNDER SM COMPONENTS.** In view of the uncertainty of the applicability of traditional ionic contamination measurement to surface mount assemblies, a mathematical study was made of the phenomena involved. A model was derived, showing that under-component

contamination behaves differently from ordinary surface contamination. By breaking down a curve obtained under practical conditions into its components, it is possible to derive separate figures for surface and under-component ionic contamination, ignoring the influence of spurious noise signals. A new software, using these techniques, has been written for this application. Comparative tests between non-destructive testing, using this software, and tests on similar circuits with the components torn off, show that there is a close correlation between the results from these two techniques, even though the under-component contamination is only partially dissolved with the former method. (Edited author abstract). 7 Refs.

## Defects

**085165 MANUFACTURING DEFECT ANALYZERS: THE MDA NICHE WIDENS.** During the years 1983 through 1993, the world market for PC board automatic test equipment is expected to experience a compound annual growth of 9.3 percent, as represented by revenues. Manufacturing defect analyzers [MDAs] are expected to show the greatest amount of revenue growth, with an estimated compound annual growth rate of 24 percent. In many areas, the distinction between MDAs and in-circuit testers (ICTs) has become blurred, so much so that manufacturers have different views as to where the MDA coverage ends and the ICT begins.

**Design** See Also AMPLIFIERS—Design; CAPACITORS, CERAMIC—Applications; ELECTRONIC CIRCUITS—Computer Aided Design; ELECTRONICS PACKAGING; SIGNAL INTERFERENCE—Crosstalk.

**085166 COST-EFFECTIVE MULTILAYER DESIGN.** Designers should consider the constraints they may impose on the printed circuit manufacturer since these can greatly affect the final cost and quality of the printed circuit board. A flow chart shows the major processes in manufacturing multilayer printed circuit boards. The processes which are common to both plated-through hole (PTH) and multilayer boards are customer input, material selection, tooling, imaging, etching, bonding, drilling, electroplating, soldering and other finishes.

Anon. *Electron Prod (London)* v 16 n 9 Sep 1987 p 35-36, 38-39, 41.

**085167 PCB FILL FACTOR CONSIDERATIONS.** The author points out that the best and least expensive way to produce a workable component placement is to do it at the drafting board. Some design and implementation details are presented.

Adams, Ira. *Printed Circuit Des* v 4 n 9 Sep 1987 p 37-39.

**085168 TERMINATE BUS LINES TO AVOID OVERSHOOT AND RINGING.** At high frequencies, the traces on a pc board act as transmission lines, so one may need to terminate them to avoid signal distortion caused by impedance mismatches. The five termination techniques presented are particularly suitable for use with high-speed CMOS logic, but can be adapted to suit other logic families as well. (Edited author abstract)

Pace, Charles (Fairchild Semiconductor Corp). *EDN* v 32 n 19 Sep 17 1987 p 227-232, 234.

**085169 COMPARISON OF PCB ROUTING METHODS.** The process of choosing a PCB router and layout system has become confusing as more types of systems are introduced. This confusion is worsened by claims made by each manufacturer. These claims usually emphasize the best features of the system being advertised rather than the features that might do the best job of designing a particular set of PCBs. This article examines the PCB design problem in order to develop a set of requirements to use in selecting a router. The features of the various routing methods are examined and compared

to these requirements.

Ritchey, Lee W. *Printed Circuit Des* v 4 n 11 Nov 1987 p 9-11, 14.

**085170 WORST-CASE TIMING ANALYSIS ENSURES BOARD RELIABILITY.** As printed circuit board designers continue pushing the limits of circuit performance, they face an increasingly critical and demanding chore: verifying the timing of new designs. Indeed, the potential for timing problems that can devastate product-development timetables multiplies when designing a complex VLSI board, where custom and semicustom ICs interact with standard off-the-shelf components in a dense, high-speed environment. The main topics are structural and functional timing, modeling functional timing, worst-case timing analysis, dealing with glitches, and weighing costs and benefits.

Rizzatti, Lauro (Teradyne, Boston, MA, USA); Wasilewski, Mary. *Comput Des* v 26 n 21 Nov 15 1987 p 90-94, 96.

**085171 COAXING TOP BIPOLAR SPEEDS FROM PROTOTYPING BOARDS.** The circuit designer working on high-speed applications like graphics or signal processing must push TTL and ECL logic chips close to their theoretical limits. Extensive computer modeling helps, of course, but the computer model just cannot predict the final effect of all the power delivery path variables. The designer accordingly turns to physical prototyping. Often that means using wire-wrappable boards, which allow device locations to be changed quickly. These boards vary in complexity from a simple two-layer board with a voltage plane on one side and a ground plane on the other to high-performance multilayer boards. Besides prototyping, they can also be used for short-run production.

Visco, P. Anthony (Mupac Corp, Brockton, MA, USA). *Electron Prod (Garden City NY)* v 30 n 7 Sep 1 1987 p 55-56, 58.

**085172 DESIGN STANDARDS FOR SMT.** Within a new technology such as SMT, we have seen a lot of excitement and confusion. Much of this has been centered around standards both for packages and for designing. In 1985 the IPC formed an SMT Land Pattern Task Group to generate a guideline for the SMT industry users. In April 1987 a document was released called IPC-SM-782. This addressed package standards and land patterns for them as well as information on design rules, fabrication and testing. Some pertinent details are outlined.

Blankenhorn, James C. *Printed Circuit Des* v 4 n 12 Dec 1987 p 33.

**085173 PACKLAYER - ALTERNATIVE TO CONVENTIONAL PRINTED CIRCUIT BOARDS.** The printed circuit board version, 'packlayer', represents an alternative to printed circuit boards with conventional solder mask systems which is not yet widely known. This alternative type does, however, offer some considerable advantages in comparison with printed circuit boards with solder resist, with the result that the higher cost involved is thoroughly acceptable. Through the development of a new system called 'Low-Cost-Packlayer', bearing the special name McSoMask, a variant has emerged within the packlayer sector. This special version combines the advantages of the packlayer with the costs of a conventional solder resist system and therefore presents a genuine alternative to the normal printed circuit board. (Author abstract)

Weiss, D.G. (Melchert Elektronik, Cologne, West Ger). *Circuit World* v 14 n 2 Jan 1988 p 42-45.

**085174 DESIGNING SMT CIRCUIT BOARDS.** Designing SMT printed circuit boards requires greater expertise than designing through-hole, leaded-component boards. Surface-mount-technology boards are typically 1.5 to 2 times more dense, are mostly of multilayer design, often have line widths of from 5 to 8 mils, can have components on both sides, and may use blind and buried vias for maximizing density. This article discusses how

standardized SMT pad sizes, spacings, and geometries ensure reliable assembly.

Markstein, Howard W. (Electronic Packaging & Production, Newton, MA, USA). *Electron Packag Prod* v 28 n 1 Jan 1988 p 52-54.

**085175 FORGING LINKS BETWEEN BOARD DESIGN AND TEST.** PC board testing generally breaks down into three categories: continuity testing, in-circuit testing, and functional testing. Requirements and features of each category are discussed. It is pointed out that connecting the board designer's data base to ATE systems is shaping up as a Herculean task, yet the potential rewards are equally great.

Milne, Bob. *Electron Des* v 33 n 7 Mar 20 1986 p 94-98, 100-101.

**085176 COMPONENT CHOICE AND PCB DESIGN FOR AUTOMATION.** Techniques, procedures and concepts which produce a PCB that has manufacturability as part of its design cycle are outlined.

Noble, Peter. *New Electron* v 21 n 2 Feb 1988 p 47-48, 51-52.

**085177 COST-EFFECTIVE PCB DESIGN.** With increasing power densities on printed circuit boards (PCBs), the dissipation of heat has become a problem. One solution is to utilise thermal planes to conduct heat away from the components to a cold wall. Thermal planes, often called heat sinks, can be used in three ways. They can be bonded to the component side of the PCB before the board is populated or they can be laminated within a circuit board to form a metal-core board. They can also be used to support areas of a flexible circuit. For the majority of circuits using leaded components, bonding to the surface of the printed circuit board is the most thermally efficient and cost-effective solution.

Haken, Brian (Printed Circuit Assoc, Fleet, Engl); Hamilton, Sheila; Hardie, Jim; Law, Ken; Willson, Ian; Wilcockson, Eric; Avery, David; Horning, Paul; Brumfield, Geoffrey; Greaves, Barry; Rayment, Terry. *Electron Prod (London)* v 17 n 4 Apr 1988 p 12-14, 16.

**085178 LASER PLOTS ON NEW EMULSION.** The installation of a new laser plotter together with the use of new high-definition films at British Telecom's Research Laboratories at Martlesham Heath has led to higher standards of productivity. It has been installed to eradicate one of the most irritating bottlenecks known to PCB designers: producing phototooling from PCB layout data. The DISC LPS720 laser plotter produces a plot in a few minutes. The control computer switches the laser beam's shutter on and off as it scans the film, building up the image as it goes. The plotting time is virtually independent of circuit complexity. The harnessing of an He-Ne laser which peaks at 630nm has necessitated the use of a new emulsion from Agfa-Gevaert. This is a dimensionally-stable red-sensitive film which accommodates the output from He-Ne lasers and which was designed specially for the printed circuit industry.

Anon. *Electron Prod (London)* v 17 n 4 Apr 1988 p 19.

**085179 FLEXIBLE PRINTED CIRCUITS: A DESIGN PRIMER.** Flexible circuits consist of conductive strips in a sandwich of insulating or dielectric material. They resist moisture and contamination and are insulated from external shorts, with holes or contact surfaces for interconnection. The mechanical and electrical characteristics of flexible circuits determine what type should be used. Total installed cost, including inspection, interconnection, fixturing and testing, must be weighed against the advantages of each. There are two general areas of application that may take the designer down different paths. The first is a circuit that will be bent or formed into

a rigid package during assembly. The second is where the circuit will be flexed continuously or intermittently during operations.

Keirstead, Chris D. (Jannock Ltd). *Assem Eng* v 31 n 5 May 1988 p 32-36.

**085180 MULTILAYER RIGID-FLEX DESIGN CONSIDERATIONS.** Rigid-flex printed wiring board (PWB) designs require careful material selection and properly specified features to produce reliable hardware. Varying material properties cause processing difficulties and thermal-stress related defects such as lifted lands, plated through hole (PTH) barrel cracks, foil cracks, foil separation, meandering, and misregistration. This article identifies design considerations for MIL-P-50884C-Type 4 multilayer rigid and flexible material combinations with plated through holes (PTH) that help produce a reliable design at a reasonable cost. Military specifications governing rigid-flex printed wiring boards are MIL-STD-2118 for design requirements and MIL-P-50884C for manufacturing requirements. 8 Refs.

Nicewarner, Earl (Fairchild Space Co, Germantown, MD, USA). *Printed Circuit Des* v 5 n 8 Aug 1988 p 16-27.

**085181 FLEX CIRCUITRY: DESIGNING FOR MANUFACTURABILITY.** A properly designed flex circuit will often be the difference between a cost-effective and a cost-prohibitive electronic interconnect. Reliability is also maximized through proper design selection. Although unique product solutions are often required for individual applications, three generic rules are appropriate for providing high reliability at minimum cost. These are discussed. An attempt is made to introduce the reader to some basic information that will aid electronic equipment manufacturers in incorporating flexible printed circuits into their product.

Becker, David (Sheldahl Inc, Northfield, MN, USA). *Printed Circuit Des* v 5 n 8 Aug 1988 p 54-57.

**085182 TO GRID OR NOT TO GRID.** Most printed circuit trace routers today use a rigid grid for trace layout. Now, since a few gridless routers are available, even more questions are added to the selection process for printed circuit design systems. This article addresses the differences between gridded and gridless routers, how they work, and where each is most applicable. While it is not always the case, the gridless router is usually best suited for handling boards with many off-grid components or with aggressive design rules. However, because of data-handling complexities inside such a router, it will usually be slower and/or less determined in its routing strategies than its gridded counterpart.

Simon, Charles J. *Printed Circuit Des* v 5 n 10 Oct 1988 p 10-14, 16.

**085183 IMPORTANCE OF SHOVE ROUTING.** Pick up a set of printed circuit board artwork and show it to some printed circuit designers. Ask them if it was routed by a manual designer or by an autorouter. Chances are that they will know immediately and be right every time. It is pointed out that with today's powerful workstations and PCs, it is now possible to obtain excellent autorouting that works with designers, not against them. With interactive shove capabilities, you no longer have to pick between quality routing and autorouting.

Wadland, Kenneth R. (Engineering Software Inc, Grafton, MA, USA). *Printed Circuit Des* v 5 n 10 Oct 1988 p 20, 22-25.

**Drilling** See Also MICROELECTRONICS—Laser Applications.

**085184 CHOOSING BACKUP MATERIALS FOR PWB DRILLING OPERATIONS.** Backup panels are flat sheets of material which serve as termination materials during the drilling of printed wiring boards (PWB's). Panels were originally used to protect expensive drilling machine tables from damage. Expensive subtooling is preserved by backup in a similar manner. Applications

have slowly evolved so that the most advanced backup materials serve as a medium through which drill bits can be cooled. This paper discusses the origins of backup materials, their effect on hole quality temperature problems, and application of air vented aluminum as backup material.

Berlin, Alvin J. *Electronics* v 32 n 12 Nov 1986 p 29-30.

**085185 GENAUGKEIT VON LEITERPLATTEN-BOHRMASCHINEN.** [Accuracy of Printed Circuit Board Drilling Machines]. The future development of the printed-circuit board is tending toward an increase in the integration of components. The results are narrower printed wiring conductors and ever smaller drill holes. When drilling PC boards, the consequence is that the demand on accuracy of the drill hole location is constantly mounting. This report defines all influencing variables, establishes their admissible tolerances and describes the effects on drilling accuracy. In addition, a procedure for testing drilling accuracy is outlined. (Edited author abstract) In German. 13 refs.

Gerlach, Burghart. *Metallverarbeitung* v 41 n 11 Nov 1987 p 539-543.

**085186 SMALL HOLE DRILLING: THE JAPANESE WAY.** Drilling techniques and philosophies are described that have made Hitachi successful in producing advanced multilayer boards (MLB). Holes from 4 to 16 mil with aspect ratios of 8:1 or more are addressed. Drilling machine functions, and variations in drill bit geometry are also included.

Kanaya, Yasuhiko (Hitachi Seiko Ltd, Tokyo, Jpn); Arai, Kunio. *Circuits Manuf* v 27 n 12 Dec 1987 p 33, 35-36, 38.

**085187 TUNE-UP FOR MICRODRILLING.** The author gives advice to those PCB producers who work with their older machines how to increase productivity in PCB microdrilling and reduce drill bit breakage. One of the methods is progressive, or peck, drilling which offers improved ability for drilling small high-aspect ratio holes, especially in hard-to-drill substrates. The practice not only allows the production of previously impossible holes, but can produce these holes without excessive bit breakage and without significantly increasing WIP time in the drilling room. The main rule in peck drilling is to drill as deeply as possible on the first peck then proceed as quickly as possible from there. Other improvements include using higher spindle speed as microdrill diameters go down checking machine stability, its squareness and collect run-out. Suggested modifications include doubling up of the spindles adding a camera to the drilling machine for better drill alignment and using a larger tool-change cassette.

Hendrik, Ed (Advanced Controls, Irvine, CA, USA). *Circuits Manuf* v 28 n 8 Aug 1988 p 63-64, 65.

**085188 SMALL HOLE DRILLING PRODUCTIVITY.** Even though significant production gains can be achieved using standard drill bit configurations with a dynamically stable machine, the realization of full productivity potential awaits major innovations in drill bit design. The author suggests using higher drilling speeds. The benefits of high-speed drilling with conventional bits in machines of high dynamics stability are: increased bit life, low cutting temperatures, absence of fiber crushing and good hole wall quality. The factors which can improve the drill bit performance are discussed. They include material chip removing ability, penetration force and self-centering. Also discussed are the factors on which drill wear depends, the four most predominant being: distance the cutting edge travels, load on the cutting edge, abrasiveness of the workpiece material, and cutting temperature.

## Electric Wiring

**085190 CHARACTERIZATION OF VIA CONNECTIONS IN SILICON CIRCUIT BOARDS.** Conducting vias, isolated by silicon dioxide from a bulk silicon wafer and used to interconnect stripline transmission lines on opposite surfaces of the wafer, are analyzed. The net VSWR (virtual standing wave ratio) and insertion loss for a single via and the crosstalk or coupling between two nearby vias are determined as a function of geometry, frequency, and silicon resistivity. For small via dimensions and frequencies up to 1 GHz, the analysis predicts low VSWR and low insertion loss, provided the silicon resistivity is greater than about 100  $\Omega$ -cm. It is shown that crosstalk can be small, and is mostly due to inductive coupling. 6 refs.

Quine, John P. (GE, Schenectady, NY, USA); Webster, Harold F.; Glascock, Homer H.; Carlson, Richard O. *IEEE Trans Microwave Theory Tech* v 36 n 1 Jan 1988 p 21-27.

**085191 ON TWO-DIMENSIONAL VIA ASSIGNMENT FOR SINGLE-ROW ROUTING.** The authors study the via assignment problem when vias are allowed to appear rowwise as well as columnwise. Previously they proved that the problem belongs to the class of NP-hard problems and therefore it is unlikely that polynomial-time algorithms exist for solving the problem. Two heuristics (HEU1 and HEU2) to solve the problem were proposed. HEU1 splits the nets before any routing is done while HEU2 assigns the nets alternately to via rows and via columns. Here they modify HEU2 so that the side of the board to which the nets are assigned first for connection is selected according to a desired ratio of board width to height. 13 refs.

**Electronics Packaging** See Also ELECTRIC CONNECTORS; ELECTRONIC EQUIPMENT MANUFACTURE—Equipment.

**085192 OBLIQUE ROUTING SYSTEM FOR FACOM M-780 SSC.** This paper describes an automatic routing system called the oblique routing system, which is used for large-scale, high-density printed wiring boards (PWBs). In addition to the conventional X and Y directions, several oblique directions are provided for the routing axes in this system. This multidirectional routing technique reduces the required wiring length and minimized the number of routing fail wires when compared with conventional methods. As a result, the propagation delay related to the interconnections of modules mounted on PWBs is reduced to enable increased package densities to be used on PWBs. This system was used to support the development of the FACOM M-780 PWBs, for which the CPU can now be mounted on a single board. (Author abstract) 3 refs.

Oda, Masahiro; Hamaguchi, Tatsuo. *Fujitsu Sci Tech J* v 23 n 4 Dec 1987 p 236-242.

**085193 DEVELOPMENT OF PACKAGING TECHNOLOGY.** Printed board assembly technology has developed rapidly since the end of the 1970's. The main driving factor has been the drastic increase in the functional content and speed of the semiconductor components. Now not only hermetically encapsulated components but also plastic packages are acceptable for demanding applications. Ericsson Telecom will employ several different types of packaging technique. Surface mounting is becoming an important method for many products although through hole mounting will still be used for long time. The author describes the development of printed board assemblies emphasizing the adaptation of packages for large VLSI circuits, and also the development of packages and its background. (Author abstract) 6 refs.

**085194 ENTWICKLUNG VON SMD-LEITERPLATTEN-REINIGUNGSVERFAHREN FÜR ZEITGEMÄSSE ANSPRÜCHE.** [Development of SMT-Printed-Circuit Cleaning Techniques for Timely Requirements]. Problems associated with cleaning of printed circuits based on surface mounted technology are considered. These circuits incorporating surface mounted devices have a high packing density and therefore all separations between components have to be reduced considerably as compared with conventional circuitry. The use of ultrasonics as a means of cleaning is pointed out. 9 refs. In German.

Connon, H.A.; Wolff, M.C. *Elektron Prod Prueftech* n 8 Sep 1987 p 50-54.

**085195 PACKAGING PRINTED CIRCUITS.** The need for integration between mechanical and electronic design systems is particularly evident in the design of printed-circuit boards and their packages. Layout tools often require 2D geometric outlines of a board based upon constraints from the electronic package. Equally important, thermal analysis conducted during electronic package design often has a significant impact on the placement of components during board layout. This level of interaction requires numerous data transfers from one type of design automation system to another. However, due to the parallel way these systems have evolved, such transfers have been difficult at best. The solution is a design automation environment that automatically provides for data transfer between design, layout, and electronic packaging. One such environment is the Mentor Graphics IDEA Series of engineering workstations which supports not only electronic packaging and thermal analysis, but also PCB design, analysis, and layout.

Wolfson, Marv (Mentor Graphics, Beaverton, OR, USA). *CAE Comput Aided Eng* v 7 n 5 May 1988 p 72, 76.

**085196 DESIGNING ELECTRONICS FOR AUTOMATED INSPECTION.** Electronic packaging technologies, such as pin grid arrays, increasingly small pitch surface mount, and double-sided assemblies are aimed towards the highest possible product density, with improved performance. The gap between inspection effectiveness and advances made in packaging technologies is becoming larger. As efforts proceed, to learn more about critical factors influencing reliability of solder joints, it is prudent to ensure that printed wiring assembly (PWA) design rules evolve to permit the broadest range of anticipated automated inspection requirements. The automated inspection technologies can be made more effective through careful design of electronics for inspection. Significant opportunities lie in both PWA layout and design, as well as electronic component design, tolerancing, and standardisation. Many inspection issues are shared, but with increased recognition of digital radiography's unique capabilities. This discussion emphasises X-ray inspection issues. (Edited author abstract). 22 Refs.

Thompson, D. (IRT Corp, San Diego, CA, USA); Stroebel, T. *Circuit World* v 14 n 4 Jul 1988 p 13-20.

**085197 AUTOROUTING TODAY'S HIGH DENSITY PCBs.** Autorouting a printed circuit board with

mixed component types immediately raises the problem of setting an effective routing grid. Use of a uniform grid diminishes routability to PGA components while a non-uniform fine line grid usually works poorly for SMDs. Our solution to this problem is a 'combination grid' capability that allows the user to specify different grids that are combined to form an overall grid for autorouting. Using the combined grid, the autorouter is able to work effectively to satisfy the requirements of PCBs with mixed component technologies. We describe how the 'evolutionary' strategy is implemented using an iterative rip-up and retry router combined with a squeeze-through and shove-aside router. This implementation has shown itself in practice to achieve a high completion rate while improving the overall quality of the routing with a balanced distribution of wires over the board and among the layers.

Cooper, John (Mentor Graphics Corp, Beaverton, OR, USA); Chyan, David. *Printed Circuit Des* v 5 n 10 Oct 1988 7p.

## Electroplating

**085198 AUTOMATING PLATING SYSTEMS FOR PWB FABRICATION - PART 2.** This is part two of a two-part article that discusses automating plating systems for printed wiring board fabrication. This part covers training, improving capabilities, and advances and developments. (Edited author abstract)

Moosmann, Kari (Electronics, Libertyville, IL, USA). *Electronics* v 33 n 1 Jan 1987 p 47-48.

**085199 CIRCUIT FABRICATION TECHNIQUES FOR SMT BOARDS.** Changes in circuit board design and characteristics are considered. With surface attachments eliminating the need for insertion of leads in through holes, surface mount device (SMD) designs include chip carriers, flat pads on external surfaces, and smaller holes (vias) that allow for more interconnections in the steadily increasing board logic capacity. An examination of the US trends exhibited in board design and fabrication through the 1980s shows a notable evolution prompted by the increasing use of surface mount technology (SMT) and multilayer board (MLB) usage. New plating techniques of the boards are described that are based on electro-deposited copper for through-hole connection. 5 refs.

Nargi, Kathy (Enthone Inc, New Haven, CT, USA). *Circuits Manuf* v 27 n 12 Dec 1987 5p between p 59 and 66.

**085200 EFFECT OF SURFACE TREATMENT ON THE ELECTROPLATED COPPER/CARBON INTERFACE.** Conventional copper electroplating of the through holes of a printed circuit board is based upon the adsorption of a tin/noble metal complex, as the catalyst for the electroless copper deposition, followed by electrolytic copper plating. This paper will describe briefly a radically different technology, based on carbon particle adsorption, as the precursor to electroplating through the hole. In both cases, the printed circuit boards undergo surface treatments. The manner in which these treatments affect the adsorption phenomena and locus of failure of electroplated model surfaces will be discussed. Adsorption studies and surface energy analyses were used to monitor surface treatment effects. XPS and SEM were used to define and image the locus of failure of electroplated model surfaces in peel and lap shear tests. The correlation of these data with advancing and receding contact angles and surface energy will also be discussed.

Pendleton, Phillip (Olin Hunt Specialty Products Inc, Palisades Park, NJ, USA). *Surf Interface Anal* v 11 n 6 Apr 1988, Proc of the 9th Symp on Appl Surf Anal, Dayton, OH, USA, Jun 3-5 1987 p 400.

## Equipment

**085201 DRILLING ROUTING, AND CUTTING TOOLS, EQUIPMENT, AND ACCESSORIES SPECIFICATION GUIDE.** This guide includes features and

specifications of equipment used to drill, separate, and profile printed wiring boards. It also includes information to facilitate selection of drill and router bits. Also included is a section containing accessories, kits, tools, equipment, and services offered by manufacturers and distributors.

Anon. *Electronics* v 33 n 4 Mar 1987 p 22-25.

## Fabrication See Also INTEGRATED CIRCUITS; INTEGRATED CIRCUITS, VLSI—Components.

**085203 FABRICATION OF A TWO-SIDED SURFACE MOUNT PRINTED CIRCUIT BOARD.** Surface mount technology (SMT) is a method of attaching leadless, short leaded, or bare chips to various substrate materials. This technology is not new, but has caught on as a method of assembling printed circuit boards and is considered the wave of the future, since it permits the packaging of a large amount of circuitry in a very small area. SMT, which may be regarded as a marriage between conventional hybrid assembly and printed circuit boards, has been used for over 30 years in the hybrid industry. This article discusses how the technologies developed by the hybrid industry were applied to a computer graphics controller consisting of a two-sided surface mount assembly printed circuit board. 2 refs.

## Heat Sinks

**085206 DEVELOPMENTS IN PASSIVE THERMAL MANAGEMENT SYSTEMS FOR ELECTRON-**

ICS. Increasing power densities within electronic equipment have led to a rise in the number of heat related problems being experienced. This paper describes the use of computerized thermal analysis techniques to optimise the design of passive thermal management systems for electronic equipment. (Author abstract)

Hamilton, S. (Enco Industries Ltd, Howwood, Scotl). *Circuit World* v 14 n 1 Oct 1987 p 22-25.

**085207 HOW TO SELECT ADHESIVE FILM FOR HEAT SINK ATTACHMENT TO PWB'S.** The main selection requirements for a material used to attach a heat sink to a PWB are good thermal conductivity, adequate bond strength, and sufficient resilience to offset assembly warpage and prevent stress transfer to delicate components or circuitry on the PWB. Such warpage and stresses occur as a result of the different thermal expansion coefficients of the PWB and heat sink. This paper discusses the subjects of choosing adhesive materials, film selection, common bonding problems and film application.

Dominic, Chris (Ablestik Lab, Gardena, CA, USA). *Electronics* v 33 n 4 Mar 1987 p 48-49.

## Heat Transfer

**085208 HEAT TRANSFER ANALYSIS OF DIGITAL TRANSMISSION EQUIPMENT WITH HORIZONTALLY ARRANGED PRINTED CIRCUIT BOARDS.** Printed circuit boards (PCBs) may be arranged horizontally in many situations, as for example in some digital transmission equipment being used in Brazil. Such pieces of equipment, known as slim racks, have a high aspect ratio (height/width) and are assembled side by side and back to back. The present work deals with the steady-state thermal dissipation in the so-called thermal unit of the slim rack made of the PCB, the magnetic shield above it and the bounding walls constituting an enclosure. The heat transfer in each thermal unit was investigated by assuming isothermal enclosure surfaces with uniform radiosities. Once the thermal paths are identified, an electric circuit analogy is employed to obtain the overall thermal resistance network. Most of the thermal resistances are temperature-dependent, so the associated nonlinear algebraic equations can be solved only by an iterative method. An experimental investigation was carried out in a module of the slim rack with simplified boundary conditions in order to verify the theoretical model. There was good agreement between the theoretical and experimental temperature fields. (Author abstract). 17 Refs.

## Impedance Matching

**085209 CONTROLLED IMPEDANCE INTERCONNECTIONS: THEORIES, PROBLEMS, AND APPLICATIONS - PART 2.** This is the second of a two part article discussing changes in the interconnection and packaging of electronic components. This part addresses controlled impedance design and crosstalk. Few solutions to the problems of designing controlled impedance interconnection systems have been provided here. However, this article is intended to increase awareness to the problem, and give some background in electromagnetic waves, which may lead to a better understanding of how to cope with increasingly stringent design, processing, and fabrication requirements. (Edited author abstract)

Fujitsu, W.S. (Hughes Aircraft Co, Irvine, CA, USA). *Electronics* v 32 n 13 Dec 1986 p 55-56.

**Inspection** See Also ELECTRONIC EQUIPMENT MANUFACTURE—Robotic Assembly.

**085210 SYSTEM FOR INSPECTING CIRCUIT BOARDS.** A printed circuit board made of translucent material and having circuit paths deposited on both sides is presented. Inspection of the circuit board for flaws is

accomplished by projecting light from a source onto one side of the board, e.g., the back side of the board, to back light and silhouette the circuit paths on the front side of the board. The light passing through the translucent board is diffused so that the back circuit paths are not silhouetted on the front side of the board. However, if a silhouette of paths does appear, it will be a substantially attenuated representation thereof in comparison to the dark silhouette of the front circuit paths. The inspection of the board is described.

Wyatt, K.L. *Tech Dig AT&T Technol* n 78 Jul 1986 p 31-32.

**085211 INSPECTING BARE BOARDS.** The Inspection/Testing of PCBs was covered previously. The author deals with the philosophy behind the test methods, an understanding of which helps in the assessment of the results. 2 refs.

Manfield, Henry G. *Electron Prod (London)* v 16 n 10 Oct 1987 p 46-48, 50.

**085212 AUTOMATED INSPECTION - ARE WE SOLVING THE RIGHT PROBLEM? - PART 2.** While inspection is the most frequent operation in circuit board assembly, it has not been widely automated because of serious shortcomings in existing inspection systems. These systems have been unable to address important classes of defects, relied on inadequate camera-based imaging, and have focused on identifying defects rather than shippable products. To achieve acceptance, inspection systems for circuit board assembly must perform like inspection personnel, only faster and more accurately. The article shows how inspection systems can improve their performance using high resolution 3-D vision and multiple quality models. 4 refs.

Juha, Mika (Photonic Automation Inc, Santa Ana, CA, USA). *Surf Mount Technol* v 1 n 3 Jun 1987 p 13-15.

**085213 LASER INSPECTION SYSTEM PROVIDES PROCESS CONTROL DATA.** Purchased to reduce the cost of detecting PCB solder-joint defects, Laser/INSPECT equipment from Vanzetti Systems Inc. was instrumental in diagnosing the cause of repeated PCB solder-joint defect patterns in circuit boards used for computer-based gasoline dispensing systems. The inspection system eliminated the cause of major PCB defects, bringing the board reject rate down to 0.7 percent from an excessively high figure while eliminating 9,000 hours of inspection and rework annually.

Roeger, Bill (Tokheim Corp, Albion, IN, USA); Morrison, Ron. *Electron Packag Prod* v 27 n 2 Feb 1987 p 128-129.

**085214 TRACKING THE EVOLUTION OF AOI.** The technology applied to automated optical inspection (AOI) of bare printed wiring board panels and artwork is evolving at a rapid and sustained pace. Systems currently in use have addressed a critical need by providing basic inspection of fine line products that could no longer be checked by manual methods. The new generation of equipment goes far beyond this, providing vastly improved throughput, versatility, and detection accuracy. The new technology uses image acquisition techniques that are unaffected by the surface condition of the metal, so inspection at the oxide stage is no longer a problem. These image acquisition units also allow detection of 1 mil shorts (measured at the base) in normal operation; while reflected light technology typically allows detection of shorts only down to 2.5 mils.

McDonald, Roy (Optrotech Inc, Billerica, MA, USA). *Electronics* v 33 n 9 Jun 1987 p 12-13.

**085215 RESOLVING PWB INSPECTION PROBLEMS WITH AOI - PART 1.** This is the first part of a two-part article comparing features of automatic optical inspection equipment. This part describes imaging systems, resolution, and speed considerations. (Author abstract)

Bunze, Victor F. (Visionetics, Brookfield Center, CT,

USA). *Electronics* v 33 n 9 Jun 1987 p 15-16.

**085216 ADVANCES IN AOI EQUIPMENT ADDRESS NEEDS, INCREASE THROUGHPUT.** From the beginning, commercially available AOI systems' scan rates were equated with throughput rates. Scan rate, however, is only one factor in the overall throughput equation. Yet many system suppliers tout their product's scan rate and virtually ignore other important elements of throughput. This paper discusses various subjects relating to throughput increase for AOI systems, including setup time, false defects, evaluation and repair.

Domres, Douglass M. (AOI Systems Inc, Westlake Village, CA, USA). *Electronics* v 33 n 9 Jun 1987 p 21-22.

**085217 HOW TO SELECT AN AOI SYSTEM - PART 1.** This is part one of a three-part article that describes factors to consider when purchasing an automatic optical inspection (AOI) system. This part discusses why AOI should be used, how to define needs, technical tradeoffs, and features. (Edited author abstract)

Benron, Hai (Orbot Inc, Woburn, MA, USA). *Electronics* v 33 n 9 Jun 1987 p 23-26.

**085218 CONSIDERATIONS FOR USING PWB VISUAL INSPECTION - PART 1.** This is the first part of a two-part article about visual inspection of printed wiring boards. Part one includes information about applications and capabilities of visual inspection. (Edited author abstract)

Kempf, Paul S. (Metron Optics Inc, Solana Beach, CA, USA). *Electronics* v 33 n 9 Jun 1987 p 35-36.

**085219 INSPECTING SURFACE MOUNTED PCBs WITH 3-D LASER SCANNERS.** Compared with 2-D imaging, the 3-D scanning method separates component and background as a function of height and shape, providing reliable inspection data. The 3-D laser scanner analyzes gray scale patterns as well as height measurements so that such variations as color, texture or the effects of ambient lighting do not influence its performance.

Trail, David K. (Synthetic Vision Systems, Ann Arbor, MI, USA); Jakimcius, Andrew. *Surf Mount Technol* v 2 n 2 Apr 1988 p 19-21.

**085220 OVERVIEW OF PWB INSPECTION/REWORK METHODS.** PWB inspection/rework capabilities can be found either on the assemble equipment in the form of component verifiers, or off the system as test rework stations. Often, off-line test units are either manual rework stations working in conjunction with automated test equipment (ATE) or automated optical inspection (AOI)/repair cells. This paper discusses both manual repair/rework stations and AOI systems. It is concluded that whichever inspection/repair method is used, manual or automated, it is vital that this step of the assembly process be closely investigated before any dollars are investigated.

Horne, Dennis (Universal Instruments Corp, Binghamton, NY, USA). *Electronics* v 33 n 11 Jul 1987 p 23-24.

**085221 RESOLVING PWB INSPECTION PROBLEMS WITH AOI - PART 2.** This is the second part of a two-part article comparing features of AOI equipment. This part covers data storage and referencing. (Edited author abstract)

**085225 INFRAROT-LEITERPLATTEN-PRUEFUNG.** [Infrared Inspection of Printed-Circuit Boards]. Using the system under review it is possible to conduct computer-aided evaluation of the infrared heat images of assembled printed-circuit boards in the operating state and compare these actual images with desired images. Wide-ranging analysis for quality assurance purposes is thus possible. (Author abstract). In German.

Wendeler, V. *F&M Feinwerktech Messtech* v 96 n 6 Jun 1988 p 263-264.

**085226 AUTOMATIC SOLDER JOINT INSPECTION.** The task of automating the visual inspection of pin-in-hole solder joints is addressed. Two approaches are explored: statistical pattern recognition and expert systems. An objective dimensionality-reduction method is used to enhance the performance of traditional statistical pattern recognition approaches by decorrelating feature data, generating feature weights, and reducing run-time computations. The expert system uses features in a manner more analogous to the visual cues that a human inspector would rely on for classification. Rules using these cues are developed, and a voting scheme is implemented to incrementally accumulate classification evidence. Both methods compared favorably with human inspector performance. 32 refs.

**Labeling** See Also BAR CODES—Applications.

**085227 HOW AND WHY TO MARK ELECTRONIC COMPONENTS, BOARDS, AND PACKAGES.** This paper discusses marking methods for electronic components and the purpose and benefits of various marking methods: direct printing, dry offset, rotary dry offset, laser printing and pad printing. Methods to produce pressure sensitive labels are compared.

Nelson, Benjamin A. (Markem Corp, Keene, NH, USA). *Electron Manuf* v 34 n 6 Jun 1988 p 8-9.

**085228 MATCHING APPLICATION REQUIREMENTS AND MATERIALS USED FOR LABELS.** Electronic industry places high demands on labels used in its manufacturing processes and environments. Because of these demands, many specialized label substrate materials, coatings, adhesives, and carriers have been developed. The specifying engineer in production or quality control (QC) is faced with decisions about labelling that can impact the bottom line significantly - positively or negatively. The

type, quality, and printing techniques used for a label can mean the difference between a smoothly running production line, or one that is plagued with downtime. This paper discusses printing methods used for labels, bar coding label construction, labels for integrated circuits, aluminum labels, labels for PCB's and the ways to specify wires and cables.

Lyon, Marty (EPC Identification Systems, Rohnert Park, CA, USA). *Electron Manuf* v 34 n 6 Jun 1988 p 23-26.

**085229 HOW TO SELECT BAR CODE LABEL MATERIALS FOR PCB IDENTIFICATION.** This paper explains how to match label characteristics with conditions PCB's undergo during manufacture, and selection criteria for a variety of label materials. The paper provides the guidelines to select bar code labels for PCB's and explains the structure of a bar code label.

Williams, James R. (Imtec Inc, Bellow Falls, VT, USA). *Electron Manuf* v 34 n 6 Jun 1988 p 38-40.

## Laser Applications

**085230 HOW LASER PHOTOPLOTTING ASSISTS COMPUTER AIDED DESIGN GROUPS.** Recently, there has been increasing interest in using the capabilities available on laser plotting systems from both captive and independent computer aided design (CAD) groups. This trend may be attributed to the increasing availability of laser plotting systems, the introduction of new capabilities by laser plotter manufacturers, and increased awareness of these capabilities by people in CAD organizations. It is beneficial to the designer that laser plotters can handle large plot files, so that the designer no longer needs to limit designs because of photoplotting costs. However, it is important for other reasons that circuit designers do not unnecessarily increase the size of their image files. This article contains suggestions that may be implemented in order to reduce the amount of image data in new designs.

**085235 EXAMINATION OF FACTORS INFLUENCING ADDITIVE/SUBTRACTIVE CIRCUIT FABRICATION - PART 1.** One of the most controversial topics in electronic manufacturing is the fabrication of circuit traces to produce printed wiring boards. The difficult problems associated with producing increasingly dense boards are exacerbated by worker safety and environmental issues, government regulation, and an increasing amount of offshore competition. This article examines some of the critical issues, problems, and trends associated with fabricating boards using additive and subtractive techniques. The first part of the article begins with an examination of the materials on which much of the attention is focused: the prepreg and laminate.

Bartos, Sara (Electri-onics, Libertyville, IL, USA); Davenport, Bill. *Electronics* v 32 n 12 Nov 1986 p 19-22.

**085236 EXAMINATION OF FACTORS INFLUENCING ADDITIVE/SUBTRACTIVE CIRCUIT FABRICATION - PART 3.** This article is the third part of a three-part examination of the issues, problems, and trends associated with fabricating PWB's using additive and subtractive techniques. This part begins with a discussion of three dimensional molded board technology. (Author abstract)

Bartos, Sara (Electri-onics, Libertyville, IL, USA); O'Loughlin, Michael; Davenport, Bill. *Electronics* v 33 n 1 Jan 1987 p 19-21.

**085237 SELECTING AND USING ROUTING EQUIPMENT FOR PANEL SEPARATION.** Cutting and dpaneling has become more complex because of the trends toward increased density and unusual PWB configurations. Routing equipment has evolved from routing bare boards to also routing loaded and surface mounted boards. With changes in boards and components, routing equipment can be adapted or refined to fulfill the PWB fabricator's requirements. This paper discusses various factors to consider when selecting routing equipment.

These factors include tool bit specifications, component heights, and electrostatic discharge (ESD). Several ways in which a board may be routed are described. Routing equipment will experience increasing integration into automated systems in the next two to three years, requiring minimal operator intervention, and improving productivity and manufacturing yields.

Stewart, Tom (Easterline Co, Torrance, CA, USA). *Electronics* v 33 n 1 Jan 1987 p 37-39.

**085238 PWB WASTEWATER PROBLEMS.** Manufacturers of printed circuits have to meet wastewater disposal regulations. The article reviews some basic wastewater concerns in which problems can arise. Some of these are pH control, heavy metals, total toxic organics, cyanides and dumping.

Frizzell, Michael A. *Prod Finish (Cincinnati)* v 51 n 12 Sep 1987 p 90-96.

**085239 ONE-WAY ETCH: THE SCIENTIFIC APPROACH TO ADVANCING THE STATE OF PCB ART.** The etching of rectangular lines on printed circuit boards by means of nitric acid is described. Copper foils of a special variety of crystallographic texture [III] has to be used for best results. The research problems, the system approach adopted, and the technical aspects of the process are briefly described.

Murray, Jerry (Circuits Manufacturing, San Francisco, CA, USA). *Circuits Manuf* v 27 n 8 Aug 1987 p 23-25.

**085240 FORCEFUL PLATING: AN AUTOMATED ALTERNATIVE TO PROGRAMMABLE HOIST PLATING SYSTEMS.** In 1981, Hewlett-Packard Co. began PCB manufacturing operations in a new facility in Boise, ID. After five years of production operation, H-P's conveyorized impingement-agitated plating system can be declared a success. The processes are segregated into the develop-and-plate line and the strip-and-etch line. The plating processes are bright acid copper, Watts nickel and bright acid tin. The etching is a conventional proprietary alkaline process. All plating operations are conventional in that the panels are submerged in the tanks, but they are unconventional in. Several respects which are described. 8 refs.

Davidson, D. Paul (Hewlett-Packard Co, Boise, ID, USA). *Circuits Manuf* v 27 n 8 Aug 1987 p 36, 38-40, 42.

**085241 NEW COPPER SURFACE TREATMENT FOR POLYIMIDE MULTILAYER PRINTED WIRING BOARDS.** A new treatment method for the copper innerlayers of polyimide multilayer printed wiring boards has been developed. Conventional oxide coatings experience acid penetration through the bonding interface during through-hole plating pretreatment. This problem was eliminated by substitution of metallic copper for the surface oxide. Promotion of the copper innerlayer adhesion to the prepreg by the oxide coating was based upon a mechanical interlocking effect caused by the minute roughness of the oxide crystals. Reduction treatment of the surface oxide layer was found to give a metallic copper surface with no changes in its morphology. Adhesion strength of polyimide prepregs to copper foils after the reduction treatment was equivalent to that of the original brown oxide coating. Acid resistance was enhanced by elimination of the oxide layer from the bonding interface. (Edited author abstract) 6 refs.

Akahoshi, H. (Hitachi Ltd, Hitachi, Jpn); Kogawa, K.; Suzuki, Y.; Wajima, M. *Circuit World* v 14 n 1 Oct 1987 p 18-21.

**085242 CRITICAL ASPECTS OF MULTILAYER MANUFACTURE.** The key to the production of high quality multilayer PWBs lies in a clear understanding of the many interactions between the chemical and mechanical processing involved. This describes some of these interactions, namely those between oxide treatment, lamination and drilling and the subsequent chemical processing steps, up to, and including, copper electroplating. Choice of oxide treatment has consequences that are not limited to the lamination and drilling operations. Process

problems, such as 'pink ring (haloing)' are discussed in the context of their sensitivity to particular stages in the manufacturing process. (Author abstract) 9 refs.

**085243 PHOTOTOOLS FOR PRINTED CIRCUIT BOARD PRODUCTION - PART 2.** Photographic films and glass plates are widely used as phototools for PCB production. In this two-part paper photographic and physical characteristics of the products are discussed as well as their differences and specific features. Terms such as contrast, density, speed, processing, etc. are explained and dimensional stability is discussed in depth. Suggestions are made for proper handling of the photographic materials. (Author abstract)

Junginger, H. (Kodak AG, Stuttgart, West Ger); Werner, W. *Circuit World* v 14 n 1 Oct 1987 p 32-35.

**085244 DEVELOPMENTS IN PCB PLATING AND CHEMICAL SYSTEMS.** Much has happened in the last few years to make it cost effective for both large and small R&D establishments to become self sufficient in the production of prototype and small batch pcbs, labels and front panels. Experiences by several British manufacturers are reported.

Walton, J. Page. *Electron Prod (London)* v 15 n 11 Nov-Dec 1986 4p between p 29 and 35.

**085245 OXIDE SELECTION TIPS FOR MULTILAYER PWB FABRICATION.** The primary reason a black, brown, or red copper oxide is used is to passivate the copper board surface, i.e., prevent the copper from oxidizing in an uncontrolled manner. If a surface is unpassivated and nonuniform oxidation occurs, water can form on the copper surface when heat and pressure are applied during lamination. Oxides also are used to increase surface area, and consequently strengthen layer to layer lamination. An important factor in choosing an oxide is the type of substrate material to be treated. Other criteria for oxide selection include cosmetic appearance, peel strength, cost and ease of operation.

Nargi, Kathy (Enthone Inc, New Haven, CT, USA). *Electronics* v 33 n 4 Mar 1987 p 19-20.

**085246 EXOTIC PCBs FOR HOT SMDs.** This article reports on three alternative configurations of PCB (printed circuit board) for use at high temperatures with surface mounted components. All three designs have been developed independently to overcome problems of thermal mismatch between conventional PCBs and ceramic SMDs, and the resulting breaks in soldered contacts. With components mounted directly onto the board, even small variations in the dimensional changes of the board and component, as the temperature fluctuated, could lead to cracks in the soldered joints.

**085248 FERTIGEN VON MULTILAYERPLATTEN MIT SIMULIERTER PIN-LAMINIERTECHNIK IM MASS-LAM-VERFAHREN.** [Production of

Multilayer Boards by a Simulated Pin-Laminating Technique according to the MASS-LAM Method]. When producing multilayer PC boards by the MASS-LAM method, accurate alignment of the various layers with regard to each other poses a problem. It was found that optical alignment methods do not provide the desired accurate congruence. Systems for lateral mating are equally subject to tolerance losses. With the so-called pin technique, alignment is obtained by inserting pins in the fitting holes of core layers, which would not be possible by the MASS-LAM method. A new, patented method now simulates this pin technique during the pressing and thus provides the advantages of a highly precise alignment by means of fitting holes, but without using fitting pins. (Edited author abstract) In German.

Limberg, Kurt. *Metalloberflaeche* v 41 n 9 Sep 1987 p 432-436.

**085249 STOCK BONDING PROBLEM: A MACRO INVESTIGATION OF MICRO FLAWS IN MIL-SPEC BOARDS.** Current manufacturing technology used to fabricate polyimide PCBs has evolved from processes used to make epoxy boards. These processes have been found to give variable bond quality between innerlayer traces/planes and the polyimide B-stage material. Results of studying standard oxidizing and several novel surface treatments demonstrated that several areas dramatically affected the quality of the copper/polyimide bond. These include strict materials control prior to laminating, incorporating an aggressive chemical copper etching, use of a minimum thickness copper oxide film to promote adhesion, and a laminating press cycle optimized for polyimide. The overall results indicate that this copper/polyimide bond could be improved to the point of structural failure rather than interfacial failure. This may be accomplished within the existing materials and technology or with new surface treatments. 3 refs.

**085255 CONTROL MATERIAL HANDLING & WATCH ELECTRONICS PRODUCTION SOAR.** The Military Avionics Div., Honeywell Inc., in St. Louis Park, Minnesota, is one of four related facilities which form a material requirements planning (MRP) system for the production of military avionics. Printed wiring assemblies are manufactured here for use in military flight control systems, target systems, and microwave systems. Two single-aisle material handling units are installed at right angles to each other in an L-shaped configuration for progressive assembly of the assemblies.

Anon. *Automation (Cleveland)* v 35 n 1 Jan 1988 p 60-62.

**085256 VIDEO TECHNIQUES AID MACHINE DEVELOPMENT.** Competitive automatic component insertion needs to be at least 99.9% reliable. To achieve this figure, individual parts or mechanisms must be even more reliable, something like 99.9%. As machines become more reliable, errors become rarer and engineers have to wait longer and longer to see examples of what is going wrong. High-speed video captures errors on film so they can be analyzed over and over again using slow motion techniques. Because the human eye is not quick enough to spot high speed errors, Ambotech Ltd used a special video camera to develop its 'Robin' component insertion machine. The first problem which came to light was asymmetric bending of axial components leads. As it lies beneath the PCB, the bending mechanism is difficult to view so the insertion head was filmed instead. Contrary to prior speculation, this revealed that the asymmetric bending was due to faulty insertion and not to faulty bending.

Noble, Peter (Ambotech Ltd). *Electron Prod (London)* v 16 n 11 Nov-Dec 1987 p 25.

**085257 NEW MATERIALS FOR SMT.** Potentially, 55% silicon density may be attainable with advanced surface mount technology (SMT). This approach has been used to replace traditional one-sided boards with PCBs densely populated on both sides with devices soldered directly to surface conductor pads. By eliminating the need to insert component leads into holes, automated assembly is expedited, board real estate is conserved, and the PCBs are simplified and less costly to make.

Shumay, William C. Jr. (Advanced Materials & Processes, Metals Park, OH, USA). *Adv Mater Processes* v 133 n 2 Feb 1988 p 37-40.

**085258 AUTOMATED EDGE CONNECTOR PLATING EQUIPMENT FOR PRINTED CIRCUIT BOARDS.** This paper describes the development of a new generation automated edge connector plating system specifically concerned with the even distribution of pre-

cious metal on the connector surfaces. Other aspects include the minimization of process chemical contamination through the development of special interstage sealing methodology, and the introduction of high speed process chemical technology. (Author abstract) 3 refs.

Hemsley, J.D.C. (OMI Int (GB) Ltd, Woking, Engl). *Circuit World* v 14 n 2 Jan 1988 p 39-41.

**085259 NEW PROCESS TECHNOLOGY FOR HIGH TOLERANCE CIRCUIT BOARDS.** The design of PCBs is highly influenced by the components being mounted on them. Holes with diameters as small as, for example, 0.008 in. and aspect ratios of 10:1 will become standard. More complicated PCBs of higher value need enhanced security and uniformity in processing. An answer to these requirements is provided by UNIPLATE, a horizontal processor developed by Schering Electroplating. To secure hole wall treatment, this system uses floodbars for forcing the solution through the holes. Together with chemicals, tuned to this very application, very high quality PCBs can be accomplished. (Author abstract)

Kreisel, R. (Schering AG, Berlin, West Ger). *Circuit World* v 14 n 2 Jan 1988 p 68-72.

**085260 LASER-DRILLED BLIND VIAS INCREASE PCB REAL ESTATE.** Printed circuit board density and circuit performance have been increased by the use of double-sided surface-mount packages, fine-line widths and spaces down to 3 mils, more impedance-controlled layers, small drilled through-holes, and buried and blind holes (vias). Laser-drilled blind holes increase device area coverage by more than 25 percent at a drilling cost less than that of mechanically drilled blind vias.

Korf, Dana W. (Interconnect Technology Inc, Beaverton, OR, USA). *Electron Packag Prod* v 27 n 2 Feb 1987 p 56-57.

**085261 VACUUM FILLS THE VOIDS IN LAMINATION.** Vacuum-assisted lamination is rapidly becoming the preferred method for fabricating high-density multilayer printed circuit boards. Laminating multilayer printed circuit boards under simultaneous heat, pressure and vacuum results in a void-free, dimensionally stable product.

Markstein, Howard W. (Electronic Packaging & Production, Newton, MA, USA). *Electron Packag Prod* v 27 n 2 Feb 1987 p 62-65.

**085262 COMPLEX MULTILAYER BOARDS VIE FOR SPACE IN JAPANESE COMPUTERS.** Chased by its developing neighbors in the low end of electronic products and strained by the recent upward re-evaluation of its currency against the U.S. and other currencies, Japan is accelerating toward the goal of becoming a major supplier of knowledge-intensive, high-tech products in the world market. VLSI, telecommunications and computers are the most important strategic areas of technology where the Japanese are concentrating their efforts. Multilayer printed circuit boards are fabricated in Japan with electroplated, 2.36-mil-wide conductors and 21:1 aspect ratios for plated through holes - 50-layer boards are planned for the next generation of mainframe computers. 28 refs.

**085266 AUTOMATIC GUIDED VEHICLES MOVE PCBs BETWEEN ASSEMBLY STATIONS.** Electronic manufacturers have for years been automating their printed circuit assembly operations. These automated operations, however, were individual assembly and test areas, or 'islands of automation'. It is the materials handling field that provides methods of physically tying these islands of automation together in the factory. One means of doing this today is with wire-guided vehicle systems. A wire-guided vehicle works in a test area carrying printed circuit boards to conveyors positioned for pick up and delivery and the test equipment.

Daebl, Donald H. (SEMCOR, Huntsville, AL, USA). *Electron Packag Prod* v 27 n 3 Mar 1987 p 42-44.

**085267 IMPACT OF PCB PROCESSING ON SURFACE-MOUNT ASSEMBLY.** Surface-mount technology (SMT), in today's context, refers specifically to the attachment and electrical connection of electronic components to interconnecting substrates (including printed circuit boards) at a planar interface. The SMT attachment process, called placement, is distinguished from the more common method of attachment by component leads through holes, called insertion or through-hole mounting. Quality in the SMT assembly process is largely dependent upon the accuracy with which component leads or contact surfaces are placed on the actual pads of the printed circuit board (PCB).

**085273 CIRCUPOSIT 3000 PROCESS SOLVES CIRCUIT BOARD BLOW-HOLE PROBLEMS.** Since the emergence of the printed wiring board industry, the plated-through-hole process has remained a cornerstone of the manufacturing sequence. The essential feature of the PTH process is the deposition of a conductive film, normally copper, onto all hole wall surfaces.

Anon. *Finishing* v 12 n 2 Feb 1988 p 31-32.

**085274 BETTER PLATING FOR PCBs.** A New electroless or autocatalytic method of copper plating is proving advantageous to electroplating in manufacturing printed circuit boards. Fully additive (which means that it can be used effectively to deposit thick plates instead of just thin preplates), the method provides more uniform plate distribution over large surface areas as well as along the wall of the multitude of small holes that the boards often contain. Moreover, the plate is stronger and more ductile than that deposited by a previous fully additive electroless copper system and is resistant to thermal stresses induced by the application of solder. The plating solution, designated the 570, is being licensed by Kollmorgen's PCK Technology Div (Melville, NY).

**085275 SURVEY OF PWB TRACE ROUTING TECHNOLOGIES - PART 2.** This is the second part of a three-part article describing automatic PWB routing techniques and algorithm implementation. This part

features automatic router implementation and discusses the subjects of copper sharing, routing by net, multilayer routing, hardware implementation and design rule checking. (Edited author abstract)

Anastasi, Robert (Cadnetix Corp, Boulder, CO, USA). *Electronics* v 33 n 14 Sep 1987 p 42-44.

**085276 ADDITIVE LEITERPLATTENHERSTELLUNG. [Manufacturing Printed Circuit Boards by the Additive Process].** The starting point for manufacturing printed circuit boards by the additive process are base materials coated with bonding agents, e.g., phenol resin paper laminates, epoxy resin paper laminates and glass-fiber-reinforced epoxy resin laminates. They are similar to those used for the subtractive system, except that the laminates are not coated with copper but with a bonding agent. Details of the process are explained by drawing comparison with the semiadditive system. (Edited author abstract) 5 refs. In German.

Steffen, H. (RWTH, Aachen, West Ger). *Metalloberflache* v 42 n 3 Mar 1988 p 131-133.

**085277 OVERVIEW OF PWB PHOTOTOOL PREPARATION - PART 1.** This is the first of a two-part article discussing many of the problems associated with creating a printed wiring board phototool. This part focuses on handling touch-up, and preparing a production master.

Anon. *Electronics* v 33 n 16 Oct 1987 p 23-24.

**085278 SURVEY OF PWB TRACE ROUTING TECHNOLOGIES - PART 3.** This is the third part of a three-part article describing automatic PWB routing techniques and algorithm implementation. This part includes advanced routing technologies and future trends. Discussed are the subjects of pin grid arrays (PGA), gridless routing and flexible field routing.

Anastasi, Robert (Cadnetix Corp, Boulder, CO, USA). *Electronics* v 33 n 16 Oct 1987 p 26-28.

**085279 USING SUBSTRUCTIVE METHODS FOR MULTILAYER BOARD FABRICATION.** The manufacturing processes involved in fabricating multilayer printed wiring boards (PWBs) are complex. With each step in the process, time and cost are added to the board. Process control throughout the manufacturing sequence, therefore, is paramount in ensuring successful fabrication. To better address PWB fabricator's questions and needs, suppliers have carefully studied the manufacturing process. Each manufacturing operation is evaluated to determine critical control parameters. Among these methods this paper discusses inner layer manufacturing, innerlayer cleaning and etching, copper oxide process, desmear and etchback and electroless copper processing.

Nargi, Kathleen (Enthone Inc, New Haven, CT, USA). *Electron Manuf* v 33 n 17 Nov 1987 p 9-11.

**085280 AUTOMATING PWB CROSS-SECTIONAL ANALYSIS TO MEET MILITARY REQUIREMENTS.** Printed wiring board manufacturers and users constantly strive to maintain realistic quality standards that permit high production yields and low scrap rates. Cross-sectional analysis is one way that both high and low volume board manufacturers can maintain a cost-effective operation; by monitoring various stages of the manufacturing process, serious and costly process deviations may be avoided. In connection with this the paper discusses the subjects of coupon preparation, system implementation and post-curing steps.

Nelson, James A. (Buehler Ltd, Lake Bluff, IL, USA). *Electron Manuf* v 33 n 17 Nov 1987 p 14-15.

**085281 PROCESSING METHOD FOR IMPROVING THROUGHPUT, QUALITY OF PWB PRODUCTION MASTERS.** Size reductions of 5:1 or greater are permitting PWB manufacturers to produce smaller, less expensive products and increase the functionality of a product within the same package area. Manufacturers are turning to sophisticated 84-pin devices in place of 64-lead

dual in-line packages (DIP's). The resulting shorter signal paths cause fewer capacitance problems. These innovations have posed new challenges in the generation of production masters, however. Four-mil lines have been achieved, and manufacturers are striving to produce lines as thin as 1 or 2 mils. To meet the needs of automated positioning equipment, these masters must conform to higher standards of precision than ever before. This paper discusses the films and processing methods corresponding to these higher standards.

McCaleb, Wick L. (Eastman Kodak Co, Rochester, NY, USA). *Electron Manuf* v 33 n 17 Nov 1987 p 25-26.

**085282 OVERVIEW OF PWB PHOTOTOOL PREPARATION - PART 2.** This is the second of a two-part article discussing many of the problems associated with creating a printed wiring board phototool. This part discusses AOI, mishandling, and phototool preparation.

Anon. *Electron Manuf* v 33 n 17 Nov 1987 p 49-50.

**085283 LEAD TRIMMING MODIFICATIONS SOLVE PWB ASSEMBLY PROBLEMS.** Although component lead trimming is just one step in the total printed wiring board assembly process, inefficient lead trimming can hinder assembly and cause board defects. Common problems include excessive wear on the blade used for trimming; material buildup on the blade; and damage caused by blade heat. Operator error may result in poor cutting, and scrap leads also may accumulate and damage a PWB. This paper describes some modifications which solve these problems. The modifications include changing blade angle and installation of cleaning pad for blades and a cooling system to lower the blade temperature.

Sengbusch, Egon (SLI Avionic Systems Corp, Florham Park, NJ, USA); Lorenzo, Joe. *Electron Manuf* v 33 n 17 Nov 1987 p 51-52.

**085284 IMAGING TECHNOLOGY TRENDS IN ELECTRONIC MANUFACTURING PROCESSES.** This paper discusses the trends in photoimaging of PCB's, the making of screens and stencils, direct etching of circuits, and imaging fine line ceramics. Other subjects include CAD/CAM systems, phototooling, IC packaging and interconnects, display technology and manufacturing environment.

Cundy, Alan S. (Dover Electronic Manufacturing, Binghamton, NY, USA). *Electron Manuf* v 34 n 6 Jun 1988 p 14-18.

**085285 HOW TO EVALUATE PCB LASER PHOTOPLOTTERS.** To produce today's fine circuit traces on PCB's, phototools need sharp edges with minimal roughness to permit the best possible resist-coated copper exposure. Sharpness and edge roughness are difficult to quantify and vary from shop to shop, although 5 to 10 percent line width is typical for roughness. These qualities are associated with photomasters' aesthetic characteristics. Three factors in designing laser plotters - resolution, spot size, and beam profile - affect plot aesthetics. As to the PCB production, it is influenced by plot quality, throughput and reliability, and this paper discusses the subjects.

Rittichier, Jeffrey (Gerber Scientific Instrument Co, South Windsor, CT, USA). *Electron Manuf* v 34 n 5 May 1988 p 8-9.

**085286 PRINTED CIRCUIT MULTILAYER PROCESSES AND MATERIALS REVIEW.** Multilayer circuits consist of layers of circuitry that are carefully registered and then laminated (pressed) together. Interconnections to the various circuitry layers are made through plated through holes. This paper gives an

explanation of the construction of multilayer boards. The various stages of production and construction materials necessary are described.

Dominici, Peter A. (Electrotek, Oak Creek, WI, USA); Kinsey, Steve. *Electron Manuf* v 34 n 5 May 1988 p 14-16.

**085287 HOW TO AVOID WET PROCESSING.** Two recently developed dry additive technologies avoid the waste handling, wet process control problems and fine-line limits imposed by today's subtractive method of board processing. The first dry process writes circuit lines directly onto a substrate from a CAD/CAM database. There is no need for artwork and its inherent limitations. The second technology, directed towards higher volume production, takes advantage of fundamental principles well understood in the photocopying field: electrostatic force transfer conductive particles from a master pattern to a substrate. Performance improvements include lower overall costs, higher circuit density and lower environmental impacts. 6 refs.

Soszek, Peter (Somich Technology Inc, Winnipeg, Manit, Can). *Circuits Manuf* v 28 n 5 May 1988 p 21-2, 24-25.

**085288 PANELS IN, PCBs OUT.** Liquid photoimaging will provide the most cost-effective and productive process for manufacturing high-density circuit boards - the continuous coating line. In this process, a plate copper panel is placed at the start of the line's conveyor system, and the entire manufacturing process takes place as the panel moves down the line. Inline AOI would be incorporated in the computer controlled process. The Microfine coating system is a unique adaptation of the slot-coating process. Unlike the coating techniques mentioned earlier, Microfine is a closed system in which the coating fluid is isolated from the environment before coating, preventing evaporation losses and contamination. The system does not depend on viscosity to determine coating thickness. Instead it accurately meters the photoresist fluid through a precision slot and deposits a uniform liquid layer onto the copper panel moving steadily past the coating slot.

**085294 INTELLIGENT CONTROLLER FOR PRODUCTION USING 'DYNAMIC SCHEDULING'.** For companies which undertake the electrodeposition of copper and tin/lead in the production of printed circuit boards (PCBs) and have complex production problems caused by the number of different PCBs and the variety of different processing needs, Dynamic Scheduling may be the answer. This article presents a review of the dynamic scheduling method.

Rickwood, Frank (Process Plant & Chemicals Ltd, Slough, Engl). *Prod Finish (London)* v 41 n 4 Apr 1988 p 22-23.

**085295 MATTER OF LIFE AND DEATH.** A brief description is given on the impact of surface mount technology (SMT) on circuit board manufacturers. The major benefit offered by SMT is in cost. The benefits are many but so are the problems. For SMT, high quality results are much more difficult and pose greater risks for investment. AB Electronics is a specialist in the field of SMT. Its facility at Rogerstone offers an almost noiseless environment. AB operates a zero defect policy. Quality auditors stalk each production line and have the power to stop the line at any time. A major part of functional testing is dynamic burn-in - accelerated life testing. AB operates a continuous flow manufacturing policy, what the company calls JIT.

Carrie, Ron (Rogerstone). *Prod Eng (London)* v 67 n 6 Jun 1988 p 18-19, 22.

**085296 HERE, JIT AND MRP II WORK IN HARMONY.** The computer industry is a logical place to find exemplary use of manufacturing software. The plant in Rancho Santa Margarita, Calif., where Unisys assembles printed circuit boards and computers is not all high technology. Instead, a combination of computers, automated and manual materials handling techniques, and just-in-time (JIT) principles helps the plant turn out its products. Central to success, are Manufacturing Resource Planning (MRP II) software and a focused factory approach.

Krepchin, Ira P. *Mod Mater Handl* v 43 n 7 Jun 1988 p 87-89.

**085297 TALK TO ME.** The industry has not yet adopted a communication protocol for automating PCB manufacturing and assembly. But, in the mean time, some large manufacturers have developed their own proprietary standards or customized systems to meet current needs. Of the several communication protocols available to the

PCB industry, one candidate is the Semi Equipment Communications Standard (SECS). The protocol and messages in SECS are directed toward equipment activities at the shop-floor level. Most of the basic documentation and initial implementation have been done in the semiconductor industry. Commercial channels can readily supply low-cost RS 232 hardware to support SECS projects. The author describes an assembly example using SECS. 2 refs.

Secrest, Jerry. *Circuits Manuf* v 28 n 6 Jun 1988 p 65, 68-69.

**085298 PADS ONLY, PLEASE.** The pads-only concept of PCB fabrication offers cost, quality and manufacturing advantages over assemblies that contain external foil paths protected by a solder mask. By eliminating defects that need rework and inspection, pads-only fabrication enhances assembly, solderability, module test and engineering changes. Thus, systems test receives boards virtually defect-free and product cost is reduced considerably. Technically, the pads-only concept completely eliminates all exposed circuit traces/foils and solder masking from the overlayers of the finished PCBs. In actual practice, however, some line traces are intentionally left on the PCB to connect circuit mounting pads to vias on the overlayers. This maintains testability, improves manufacturing ability and facilitates engineering change orders (ECOs).

**085301 NEW METHODS OF SURFACE AREA MEASUREMENT AND CURRENT DENSITY CONTROL IN PCB MANUFACTURE.** New methods of surface area measurement by electrolytic means have been introduced by a British company. Two instruments, known as the DIM and MIM systems respectively, are available. The instruments differ in their method of measurement and applications, but both measure the conductive surface area of photo-resisted boards to a high degree of accuracy and can convert this area measurement via an interface unit to a rectifier current output, thereby controlling plating current density. (Edited author abstract).

Menzies, G.D.M. (PMD Chemicals Ltd, Coventry, Engl). *Circuit World* v 14 n 4 Jul 1988 p 27-28.

**085302 ANALYSIS OF MASS TRANSPORT AND OHMIC LIMITATIONS IN THROUGH-HOLE PLATING.** Fluid flow, mass transfer, and ohmic resistance are analyzed in through-hole plating of multilayer printed circuit boards. The analysis indicates that in holes in high aspect ratios plated under practical conditions, the ohmic rather than the mass transport resistance imposes the critical limitation on the current density at which through-holes may be uniformly plated. An ohmically limited current density is quantitatively identified as a function of the hole dimensions, the conductivity, and the deposition kinetics. It is shown that the ohmic limitation is highly sensitive to the hole dimensions, especially its length. The maximum current density which provides deposits of acceptable uniformity can be increased by increasing the electrolyte conductivity, the electrode polarization, or by modifying the hole geometry. (Author abstract). 14 refs.

**085305 ONE FABRICATOR'S EXPERIENCE WITH PRINTED CIRCUIT BOARD DIRECT IMAGING.** This paper reports the initial results of using a direct laser imaging system by a PCB manufacturer. The benefits of direct laser imaging are described, the results of the testing of new films for use with the visible argon laser systems are reported and recommendations for the future are discussed.

Feltham, Steve (Automata Inc, Sterling, VA, USA); Jean, Louis. *Electron Manuf* v 34 n 8 Aug 1988 p 16-19.

**085306 PRINTED CIRCUIT BOARDS FOR INDUSTRY.** The article describes the various steps in producing boards with plated through holes. In recent years, the demands for increasing packaging density of PCBs has led to the widespread use of surface-mounted devices, whereby both active and passive components can be attached to a substrate without the use of leads or their corresponding holes. The small size of such components, together with the fact that they can be soldered to both sides of a board, enables a greater number of components to be accommodated per unit area. Tin-lead or solder plays an important part in the production of PCBs, where it is able to carry out several functions with high reliability. The review concludes with profiles of several PCB manufacturers in the UK.

Karpel, S. *Prod Finish (London)* v 41 n 7 Jul 1988 p 6-8, 16.

**085307 FACTORS WHICH AFFECT OUTGASING AND HOLE-WALL ADHESION IN**

**THROUGH-HOLE PLATING.** This article examines what takes place inside the hole at various stages of manufacture of PCB's by the subtractive method using electroplated tin-lead as a metallic etch resist which is subsequently fused. The topics considered are the following: 1) The quality of laminate used, with regard to: (a) the adhesion between glass and resin; (b) the amount of air encapsulated in the resin at the pressing stage; and (c) the degree of polymerization of the resin and dimensional stability of the laminate. 2) The drilling parameters, e.g. penetration rate, rotation speed. 3) The significance of the electroless copper process used. Hole-wall pull-away and resin recession treated in the same section on general hole-wall adhesion since these phenomena are related. 2 refs.

**085308 IMPACT OF MICROWAVE THEORY ON MLBs FOR HIGH-SPEED DIGITAL APPLICATIONS - DESIGN, PRODUCTION QUALIFICATION.** Multilayer boards for high-speed digital applications are no longer solely substrates for the electrical interconnections needed but play an active role regarding the overall performance of electronic assemblies. In the general part of this paper all the important parameters regarding achievable impedances and their tolerances are discussed in detail. The second part is concerned with the practical realization of Microwave Theory on a selected example of a high-speed MLB. (Author abstract) 6 refs.

Angstenberger, A.L.M. (LEITRON Leiterplatten-Electronic GmbH, Gmuend, West Ger). *Circuit World* v 14 n 1 Oct 1987 p 39-43.

**085309 MOLDED CIRCUITS REQUIRE ATTENTION TO NEW DESIGN TECHNIQUES.** Molded circuit boards offer designers creative opportunities that lead to new electronic products. But before you can take advantage of these molded circuits, you must consider new and demanding design guidelines. Fortunately, one can handle these additional considerations in a straightforward manner. It is shown that by carefully using surface-mount-technology (SMT) components can reduce the number of holes and thus the number of weld lines in the assembly can be reduced to strengthen the board. (Edited author abstract)

Williams, John (ICI Electronics, USA). *EDN* v 33 n 2 Jan 21 1988 p 161-164, 166.

**085310 GIVE NEW STRENGTH TO MULTILAYER BONDING.** The process is an immersion-tin process, now being evaluated as a substitute for the familiar black-, red- or brown-oxide processes. Both types of processes promote the inner-layer adhesion of multilayer assemblies, but attention should be given first to the advances that the familiar oxide process is undergoing. Both approaches are discussed. 5 refs.

Smith-Vargo, Linda (Electronic Packaging & Production, Newton, MA, USA). *Electron Packag Prod* v 27 n 2 Feb 1987 p 52-55.

**085311 USING FLUOROPOLYMER SUBSTRATES FOR HIGH SPEED, DIGITAL CIRCUITS.** A circuit material R02800 was designed to meet the electrical and mechanical requirements of high speed, high density, digital PWB's. This material was developed as part of a program which include production of circuit materials, flexible circuits, multilayer PWB's a high performance connector system, and a resistive foil for terminating resistors. The proprietary material is a highly filled, fluoropolymer composite designed for high performance multilayer boards. The key electrical properties are a dielectric constant of 2.9 and a dissipation factor of

0.0012 at frequencies as high as 10 GHz. These properties are stable over wide variations in temperature, frequency, and humidity.

## Measurements

**085312 AUTOMATISCHES MESSEN DES LAGENVERSATZES IN MEHRLAGENSCHALTUNGEN.** [Automatic Measuring of Layer Offset in Multilayer Circuits]. Knowledge of the inner layer offset in the production of multilayer circuits is of central importance for quality assurance. The article presents a test system which enables nondestructive inspection by means of radiography and subsequent image processing. Automatic measurement of the layer offset on the production line permits early intervention in the process and thus minimizes rejects of the expensive multilayer circuits. (Author abstract) In German. 2 refs.

Kellner, Rolf. *F&M Feinwerktech Messtech* v 96 n 5 May 1988 p 193-196.

## Nondestructive Examination

**085313 REAL-TIME RADIOGRAPHY FOR ELECTRONICS RELIABILITY ASSESSMENT.** X-radiography is commonly used for nondestructive evaluation (NDE) of microelectronic circuits and components. With the development of real-time microfocus systems, however, radiography becomes a much more rapid and efficient - and in some cases the only - means of assuring reliability. Two simultaneous capabilities have been joined - a real-time ability so that the part can be viewed while it is remotely manipulated and the microfocus x-ray tube, which can provide very sharp and magnified images, virtually without distortion. The combination of these two mutually complementary capabilities permits rapid and exact visualization of details in many types of electronic hardware and assemblies. The Technology Support Division of Hughes Aircraft Co. currently employs a Magnaflux Realtime Microfocus X-Ray System in the reliability and failure analysis of electronic components, assemblies, and related hardware. Some specific examples of this are presented. Examples of analyses relating to printed wiring board (PWB) assemblies will include identification of improperly formed solder joints, location of a potential open trace in an encapsulated assembly, and imaging of incompletely plated throughholes. (Edited author abstract)

## Process Control

**085319 MICROSECTIONING OF PCB'S AS A PROCESS CONTROL TOOL.** Microsectioning of printed circuit boards (PCB's), including rigid, flexible, and rigid-flex combinations, has long been widely recognized as an important quality assurance tool. MIL-P-55110D, with Interim Amendment 2, the current military specification for rigid PCB's, and MIL-P-50884C, the current military specification for flexible and rigid-flex printed circuits, require that test coupons on every multilayer panel be microsectioned in the 'as produced' condition and after thermal stress (solder float) conditioning. These microsections are then evaluated to determine compliance with various dimensional and physical requirements. These inspections form one of the bases for acceptance of the actual production boards on the panel. Many commercial, aerospace, computer, and communication equipment corporations have specifications with similar requirements. Many PCB manufacturers use microsectioning for in-process inspection to increase yields and avoid costly rejection of product at final inspection.

This paper discusses microsectioning procedures, encapsulation, grinding of specimens, post-cure grinding, polishing compounds and etching of specimens.

McCrory, Brian (Delsen Testing Lab Inc, Glendale, CA, USA). *Electron Manuf* v 34 n 7 Jul 1988 p 14-17.

**Processing** See Also IMAGING TECHNIQUES—Automation; SOLDERING—Defects.

**085320 PAINFUL PROCESSING: ANAESTHETIC SOLDER MASKS?** Problems in processing of printed circuit boards (PCB), like troubles with adhesion, bleeding, bubbling, slipping and post solder residue in screening solder masks are considered. High solid content, low cure time solder masks are sought to obtain better definition on today's denser and more complex boards.

Murray, Jerry (Circuits Manufacturing, San Francisco, CA, USA). *Circuits Manuf* v 27 n 12 Dec 1987 p 26, 28.

**085321 AUTOMATED WET PROCESSING.** The most complex operation in making a circuit board is wet processing. Etching, electroplating, stripping, developing and electroless plating combine to involve a myriad of chemistries, all of which must be kept at concentration. Simultaneously, immersion times, temperatures, current densities and rinses must all be controlled, and these parameters vary throughout the millions of different boards now being made. Then, at the end of the line, waste treatment waits to be automated. Wet processing automation at various circuit board manufacturing plants is described.

Murray, Jerry (Circuits Manufacturing, San Francisco, CA, USA). *Circuits Manuf* v 28 n 2 Feb 1988 p 48-50, 52.

**Production** See Also BAR CODES; COMPUTER AIDED MANUFACTURING—Automation.

**085322 AUTOMATION AND SOLDER PASTE PRINTING GUIDELINES FOR SMCs.** Printed circuit boards (PCBs) containing surface mount components (SMCs) exclusively or a combination of both SMCs and insertion mounted components (IMCs) are becoming more common in the electronics industry. The increased use of high density boards with SMCs and IMCs is creating new challenges. They include establishing effective printing guidelines, and utilizing equipment that can reliably produce completed boards, both from a printing and an assembly/solder standpoint. With automation comes the need for standardization of the entire process. The equipment will vary, but there must be a common factor: total process control. This only can be achieved if manufacturers adhere to printing guidelines such as those discussed in this article.

**085323 LEITERPLATTEN-HERSTELLUNG UND BEGLEITENDE QUALITAETSSICHERUNG.** [Printed-Circuit Board Production and Accompanying Quality Assurance]. In this article readers learn about PCB production at the Italian Zincoelcere company, a member of the Teknecomp Group (Olivetti) and one of Europe's leading firms in terms of invoiced sales and production technology. At the centre of attention are the main phases of the overall mechanical working cycle, notably the lamination of semifinished stock, etching and board finishing. The necessary inspection and test operations are also considered. (Author abstract) In German.

Mazzolini, Sergio. *Metalloberflaeche* v 42 n 5 May 1988 p 225-228.

**085324 LAGEBERICHT ZUR LEITERPLATTEN-FERTIGUNG: BEARBEITEN VON LEITERPLATTEN.** [Situational Report on Printed-Circuit Board Production: Mechanical Working of Printed-Circuit Boards. Applications in Practice - Manufacturers' Experiences - Machine Systems - Tool Developments]. The purpose of this situational report is to spotlight the state of the art and a trend over the next few years of the mechanical

working of PCBs. So as to be able to sketch a complete picture, interviews were conducted with a representative selection of users, tool makers and machine builders. The sometimes critical comments are the outcome of the interviewees conflicting view-points and our own critical assessment of the situation. Rather than being regarded at individual levels, such views are intended as helpful observations. (Author abstract) In German.

Wiendl, Josef; Marka, Rudolf. *Metalloberflaeche* v 42 n 5 May 1988 17p.

**085325 MODULAR CLEANROOM DESIGN.** Printed circuit board (PCB) and hybrid microelectronic assembly (HMA) photoplotting operations have long been plagued by microscopic airborne dust that causes minute pinholes in the production film used. Opaquing time required to eliminate these pinholes is costly. To combat these problems, we have installed an interconnected, 600 sq. ft Class 100, multi-cleanroom complex in our film-production facility. This facility houses our laser photoplotter, which produces 24 in. x 36 in. film in 15 min and a vector photoplotter, which produces 48 in. x 60 in. film. Also included in this cleanroom complex is a 300-Megabyte digital design system. A computer autoroute system permits us to generate PCB and HMA circuitry from a customer's schematic. Both the design system and the autorouter produce the input tapes for the photoplotters.

Ramirez, Jose B. (Computer Circuit Inc, Cardena, CA, USA). *Printed Circuit Des* v 5 n 8 Aug 1988 p 36-38.

**085326 AUTOMATION AIDS PCB PRODUCTION.** It is reported that Teli, the industrial division of the Ministry of Telecommunications in Sweden, recently made the decision to commence production of its own printed circuit boards in a factory designed to be one of the most advanced of its kind in Europe. Now commissioned and in operation, the processing equipment comprises two plating lines - one electroless and one electrolytic. The electroless plating line - incorporates MLB permanganate desmear and plated-through hole (PTH) electroless copper stages. A special feature is 45° mechanical agitation which improves the turbulence inside small holes. The electrolytic line, equipped with two 'A' shaped transporters, includes electrolytic copper and tin/lead processing.

Anon. *Electron Prod (London)* v 17 n 8 Aug 1988 p 20-21.

**Protective Coatings** See Also TINNING.

**085327 TIPS FOR SALVAGING PARYLENE-COATED PWB's.** High performance printed wiring boards that require conformal coating for moisture and mechanical protection are generally expensive to produce; manufacturers hesitate to discard them if they malfunction. Therefore, it is important that the coating material selected be removable for component testing and replacement. Parylene vacuum-deposited conformal coating is used for various military and commercial board protection applications. The advantages of this coating include high dielectric strength in very thin layers (as much as 5kV/mil); complete conformity of the coating on flat surfaces, around corners, on sharp edges, and other components; and high resistance to solvents and moisture. This paper discusses vacuum deposition of parylene and the methods of its removal by local heating, air abrasive method or mechanical removal.

**085328 JAPAN'S SMOBC OPTION: COAXING THE UTMOST OUT OF A CHEMICAL REACTION.** Because of their many benefits, all-copper SMOBC boards with plated through-holes are increasingly prevalent. The elimination of solder slivers and improved solder mask adhesion are not the least of their benefits. The current prevailing methods for fabricating this type of board are

relatively cumbersome and costly, and are not conducive to high yields. Manufacturers often express a desire to have a simple dip that would act as an etch resist and eliminate steps in these processes for making SMOBC boards. Such an alternative is now available.

At the center of attention are the main phases of the overall mechanical working cycle, notably the lamination of semifinished stock, etching and board finishing. The necessary inspection and test operations are also considered. (Author abstract) In German.

Mazzolini, Sergio. *F&M Feinwerktech Messtech* v 96 n 5 May 1988 p 187-190.

**085330 PROZESSSICHERUNG BEI DER MULTI-LAYER-HERSTELLUNG.** [Process Assurance in Multilayer Production]. The concept of process assurance is becoming more and more important. Active process assurance is an effective quality assurance measure. Good possibilities of describing process assurance by means of a practical example are afforded by the control of a production chain with numerous greatly differing individual processes, such as is called for in the production of multilayers. (Author abstract) In German.

Winkelmann, Robert. *F&M Feinwerktech Messtech* v 96 n 5 May 1988 p 191-192.

**Quality Control**

**085331 QUALITY CONTROL METHODS FOR ANTICIPATING PROBLEMS ON PRINTED CIRCUIT BOARD PLATING LINES.** This paper presents a case history on the implementation of touchscreens for improved monitoring and control of a PCB plating line. Touchscreens, new measuring methods, and the use of real-time statistical control have resulted in a significant increase in board quality. The touchscreens have given line operators new understanding of the process leading to increased motivation and participation.

Watson, Rick (Texas Instruments, Austin, TX, USA). *Electron Manuf* v 34 n 6 Jun 1988 p 35-37.

**Reliability** See LOGIC DEVICES—Reliability.

**Repair** See Also INTEGRATED CIRCUIT TESTING.

**085332 STICKY SOLUTION.** Use of the proper processes, equipment and materials optimizes results and ensures process repeatability of surface mount rework and repair. But once the optimum processes and equipment have been chosen, the proper selection of materials, i.e., flux, solder paste, epoxies, solvents, etc., becomes tantamount to a successful rework operation. Using the proper materials is crucial because the rework process often pushes materials outside the range of operating parameters for which they were originally formulated. This is most apparent with flux. The following establishes flux as an essential in the rework process and examines the viability of paste flux. Paste flux, a relative newcomer to SMT, appears to eliminate many of the problems associated with traditional liquid flux formulations in the harsh world of rework and repair.

Martel, Michael L. (Conceptronic US Ltd, Gonic, NH, USA). *Circuits Manuf* v 28 n 2 Feb 1988 p 73, 75-76.

**085333 BOARD REPAIR - THE ECONOMIC ANSWER.** The electronics industry is now expanding at a considerable rate, but not so the board geometry. Track

sizes are generally still at 0.010 in. but even this size puts considerable strain on the repair operations. The move to surface mount technology also has the effect of reducing track sizes. The quality of repair which may be produced by conventional methods can not rival the visual quality which may be obtained by parallel gap welding. This paper examines in a practical way the process and methods which can be employed to save valuable material. (Author abstract)

Willis, R. (Dimension 2 Technology plc, Reading, Engl). *Circuit World* v 14 n 3 Mar 1988 p 74-75.

**085334 TOOLS AND TECHNIQUES FOR REWORK STATION SET-UP AND REPAIR.** Many manufacturers realize that printed wiring board (PWB) rework and repair, engineering changes, and damaged board scrapping cost organizations thousands of dollars each year. As board assembly technology advances, however, assemblers' ability to perform non-destructive rework and repair diminishes. Three major influences contribute to this trend: designers often do not incorporate repairability factors into board designs; manufacturing processes do not permit repairability; and the skills, knowledge, tools, and equipment are inadequate to perform a job correctly. Many PWB assemblies are 10, 20, or 30 times smaller than their counterparts of a decade ago. Components, circuit configurations, and packaging are sophisticated to such an extent that they only can be handled by people trained in rework techniques, using tools designed especially for a task. The paper shows how rework stations equipped with the proper supplies and a skilled staff can facilitate repairs on PWB, specifically component removal and conformal coating removal.

Bausell, James (Pace Inc, Laurel, MD, USA). *Electronics* v 33 n 11 Jul 1987 p 12-14.

**085335 REDUCING WASTE WITH PROPER PWB REWORK/REPAIR STATION SETUP.** The paper discusses the operations which take place at PWB rework/repair stations including testing, desoldering, faulty component removal and cleaning. Methods of waste reducing are mentioned. It is stressed that testing components and boards before and during assembly ensures product integrity, and provides the key to reducing rework and repair expenditures, and avoiding backups and delays. Rework and repair are facts of life in electronic production. They can, however, be managed efficiently and cost effectively through testing, process implementation, and proper equipment use.

Logee, Curtis (EPE Technology, Manchester, NH, USA). *Electronics* v 33 n 11 Jul 1987 p 19-20.

**085336 SERVICING SOLID-STATE CIRCUIT BOARDS.** Rapid changes in electrical/electronic technology have taken place since solid-state equipment has been installed. For such items as DC drives and similar equipment, it is not uncommon to find that replacement printed circuit boards for the units either are no longer available, need to be custom produced, or are long-delivery items. Thus, it is increasingly the plant electrician's job to repair this type of equipment to keep it running. The author describes a servicing procedure which has been developed for circuit board repair. The servicing program includes the logging of information on the various types of drives and cross referencing the solid-state devices. This information is drawn upon when testing transistors and diodes, replacing parts, and repairing the circuit boards. Obtaining information on the various types of drives is the basis of the servicing procedure.

Huseman, John M. (Purdue Univ). *ECM Electr Constr Maint* v 86 n 2 Feb 1987 p 66-68.

**Robot Applications**

**085337 ROBOT EXCELS AT HIGH-MIX PRODUCTION.** Demand for higher board densities drove the Government Systems Div., Control Data Corp., Minneapolis, to search for an automatic process for implementing new types of surface-mount technology. Manufacturing faced an investment decision: buy either fixed automation

(dedicated machines) or flexible automation (robotic workcells) to populate printed wire boards. Because flexibility was paramount, Control Data installed a robotic workcell from Adept Technologies, San Jose, Calif. This article discusses various aspects of the application.

Oquist, Michael R. (Control Data Corp, Minneapolis, MN, USA). *Automation (Cleveland)* v 34 n 11 Nov 1987 p 68-70.

**Robotic Assembly**

**085338 OVERVIEW OF ROBOTICS FOR PRINTED WIRING BOARD ASSEMBLY.** The use of robotics in printed wiring board assembly is expanding in two ways. First, virtually every process on a board assembly line can be automated, thus facilitating automated, integrated production. Second, off-line programming via downloaded design data makes low volume production feasible. This paper discusses selection criteria, assembly control, accuracy and repeatability of robotics in PWB assembly.

Dudley, John (Seiko Instruments, Torrance, CA, USA). *Electronics* v 33 n 1 Jan 1987 p 40-41.

**085339 VIEWING THE ROBOTIC WORKCELL AS A SYSTEM.** Once an electronics manufacturer decides to automate a printed circuit board assembly line, it soon becomes apparent that what is needed is not merely a robot but rather a complete robotic workcell. The key to successful automation is to look at the entire system, reviewing and analyzing the whole manufacturing process. The goal is not superb robotics, but rather the attainment of an efficient, flexible production system, which adapts easily to future needs and component changes.

Michaels, Robert H. (Heller Industries Inc, Florham Park, NJ, USA); De Angelo, Don. *Electron Packag Prod* v 27 n 11 Nov 1987 p 46-47.

**085340 ELECTRONIC PARTS PRESENTATION USING VIBRATORY BOWL FEEDERS.** This paper presents the results of experiments using custom tooled vibratory bowls for presenting non-standard electronic parts to a robot for insertion on printed circuit boards. (Author abstract) 19 refs.

Schroer, Bernard J. (Univ of Alabama at Huntsville, Huntsville, AL, USA). *Robotics* v 3 n 3-4 Sep-Dec 1987 p 409-419.

**085341 THRU-HOLE SYSTEM ACHIEVES QUALITY AND FLEXIBILITY.** Thru-hole insertion is being used by every major electronics manufacturer building printed circuit boards. This requires that reliability, flexibility and quality be included when getting the pegs (component leads) into the holes of the circuit board. Product mix, shorter production runs, engineering changes to the product, faster delivery requirements, CAD/CAM, Just-In-Time manufacturing strategies and CIM lines all require high degrees of reliability and flexibility. Quality assures longterm reliability in the operation.

Holcomb, Gregory W. (Chad Industries, Orange, CA, USA). *Rob World* v 6 n 5 Jun 1988 p 38-40.

**085342 COPPER SURFACE FINISH PROMOTES SOLDERABILITY.** Benzotriazole prevents surface tarnishing and oxide formation, and promotes surface wetting and solderability of copper surfaces. A copper benzotriazole process consists of four main steps: cleaning, benzotriazole application, water rinsing and air dry.

Benzotriazole application methods, and the wave-soldering criteria on the copper benzotriazole boards are discussed. 8 refs.

Ho, Man Kei (Digital Equipment Corp, Kanata, Can). *Electron Packag Prod* v 27 n 10 Oct 1987 p 39-41.

**085343 APPLICATION OF DRY FILM SOLDER MASK RESISTS.** Since their development in the mid-1970's, dry film solder mask resists have offered an efficient, versatile alternative to more traditional liquid screen solder masks in the production of printed wiring boards. As printed wiring boards start to use combinations of surface mount and leaded through hole components with high densities, manufacturers are using dry film solder masks even more. Dry film solder masks can accurately register and reproduce phototools and tent via holes with films. In addition, it is successfully being used with automation. The compatibility of dry films with denser boards and improvements in production economics are keeping the growth of dry film solder masks ahead of the PWB production growth. This paper discusses the types of dry film solder masks, their advantages, their comparison with liquid solder masks and cost saving results.

Cassady, Kim (DuPont, Wilmington, DE, USA). *Electronics* v 32 n 10 Sep 1986 p 28-30.

**085344 METHOD TO IMPROVE WAVESOLDERING QUALITY.** Instead of continually trying to control all process variables, a soldering process was developed which is far less sensitive to most variables and requires only a few PWB design considerations. It is more effective to design a process which reduces the variables and their influences than it is to control them. The process begins with the PWB design. Lead-to-hole clearances are maintained at 10-18 thousandths to optimize solder wicking of plated through holes, while limiting the possibility of voids. Pad sizes and configurations are designed to limit heat sinking and bridging effects. Solder masks are used on all double-sided boards, and single-sided boards with dense circuitry patterns. These design considerations, when combined with proper lead forming, are sufficient to control most defects resulting from design parameters. This soldering process has resulted in substantially improved solder joint quality. Printed wiring boards once considered difficult to solder now routinely exceed specification.

Sholley, Craig B. (Oven Industries Inc, Mechanicsburg, PA, USA). *Electronics* v 32 n 10 Sep 1986 p 32-33.

**085345 COMMON QUESTIONS ABOUT SOLDER MASKING.** Solder masks have evolved to meet the increasingly stringent demands of the printed wiring board industry. As a result, PWB manufacturers are faced with an increasing number of complex choices in materials and application technologies. Despite the proliferation of products and application methods, the PWB manufacturer's job can be simplified when the correct material and application method for a particular job is determined. Making that determination is not easy and involves many considerations. This article answers some of the frequently asked questions about materials and process technologies available to meet PWB design requirements.

Denkler, John D. (M&T Chemicals Inc, Rahway, NJ, USA). *Electronics* v 32 n 10 Sep 1986 p 36-40.

**085346 SOLVING PWB SOLDERING PROBLEMS TO IMPROVE QUALITY.** The increasing demand for reduction of solder joint defects and for 100 percent solderability requires a careful examination of the soldering process. The author notes that with all the repair and rework stations available, there are very few solderability testers being introduced. Repair and rework are unnecessary if boards and components are solderable. Touchup and rework can be reduced significantly and in some cases eliminated, providing a tremendous improvement in product reliability and an equally impressive cost reduction. This improved reliability will not be achieved by installing new soldering machines nor by using more active fluxes. In addition, this program is not difficult or expensive to

initiate. An understanding of the soldering process and its importance is required to implement this program; also required are carefully developed process controls. The program requires the backing of an educated management, and above all, the determination to do the job right the first time.

Woodgate, Ralph (WoodCorp Inc, Brewster, NY, USA). *Electronics* v 33 n 3 Feb 1987 p 29-30.

**085347 DOD-STD-2000: THE ALL-IN-ONE SOLDERING STANDARD, PART 1.** DOD-2000 is the first tri-service (Army, Navy, Air Force, DLA) agreement as to what the DOD needs in products from manufacturers. It is a mandatory minimum requirement for soldering/wiring practices. By incorporating 33 different federal, military and industry specifications and standards into one DOD-2000 should improve MIL spec system efficiency. In its entirety, DOD-STD-2000 addresses the spectrum of solder and wire connections normally defined as standard and miniature. It was written as a guideline defining the technical criteria essential to electrical connections and wiring within equipment fabricated by or for the Dept. of Defense. Other requirements not directly addressed, such as those for micro-miniature soldering of thin/thick film microelectronic assemblies, will be imposed by reference to other standards (for example, MIL-M-38510).

Roy, Roland (Royer Manufacturing, Chelmsford, MA, USA); Grinovich, Ed; Worthington, Shari. *Circuits Manuf* v 27 n 8 Aug 1987 p 46-48, 50.

**085348 BATCH VS IN-LINE VAPOUR PHASE SOLDERING.** In the early days of surface mounting when the batch vapour phase solder reflow process was adopted as a fabrication technique by hybrid producers, there were no objections to the throughput capabilities of systems since hybrid manufacture centered on batch techniques: standard batch tanks could more than cope with production requirements. However, with surface mounting now being applied to printed circuit assemblies, where large board sizes and high production rates are required, the question of batch system throughput has become a subject of discussion. Pertinent production guidelines are considered.

Booth, Richard (IV Products Ltd). *Electron Prod (London)* v 15 n 11 Nov-Dec 1986 p 21-23.

**085349 SOLVING PROBLEMS IN HOT AIR SOLDER LEVELING.** The process of solder coating and hot air solder leveling (HASL) has been regarded with both interest and aversion by printed wiring board (PWB) fabricators since its introduction. As the process and suppliers matured, several points became obvious: system simplicity was preferable; a large solder pot had greater thermal stability than a small pot; and vertical processing, no matter how advanced, had drawbacks inherent in the way the board was handled. A compact horizontal system has been introduced recently, making the equipment advantages available to the average size facility. The compact design provides greater reliability and ease of maintenance than standard units. By combining this equipment with conveyorized pre-cleaning and post-cleaning units, a total process system for hot air leveling can be realized.

White, Butch (Gyrex Corp, Santa Barbara, CA, USA). *Electronics* v 33 n 6 Apr 1987 p 20.

**085350 COMMON PROBLEMS WITH HOT AIR SOLDER LEVELING - PART 1.** This is the first part of a two-part feature about common problems encountered during hot air solder leveling and recommended solutions. Part one describes problems and solutions associated with solder appearance and solderability as well as solder leveling problems. (Edited author abstract)

Fischer, Ivo Jr. (Voss Electronic Inc, Sant Ana, CA, USA). *Electronics* v 33 n 6 Apr 1987 p 22-23.

**085351 HOW TO EVALUATE HOT AIR SOLDER LEVELLING SERVICES.** This paper helps a PWB fabricator to determine whether a hot air leveling system

should be purchased. In addition to the basic equipment price, other factors which should be considered when buying HASL equipment include: operating costs, overhead, equipment depreciation, interest, and floor area. Often overlooked, but equally important are maintenance costs and the cost of rejects. It is important to understand what all the costs are, and not just the purchase price.

Fishfeld, Albert (Summatek Group, Trenton, NJ, USA). *Electronics* v 33 n 6 Apr 1987 p 24.

**085352 OVERVIEW OF HOT AIR SOLDER LEVELING.** Hot air solder leveling is a method of ensuring and preserving the solderability of a PWB. In hot air solder leveling, a clean, fluxed PWB is dipped vertically into a bath of hot liquid solder. Next, both sides of the board are exposed to hot air jets while the board is withdrawn from the solder. Solder leveling equipment clears all holes of solder, removes excess solder from conductor surfaces, and uniformly levels the solder to a predetermined thickness (within the limitations of this somewhat geometry dependent process). Operating parameters can be controlled accurately to achieve consistent results. This paper discusses selection criteria for hot air solder leveling equipment and some changes influencing the process.

Anon. *Electronics* v 33 n 6 Apr 1987 p 27.

**085353 HOW TO PREVENT THERMAL SHOCK USING TEMPERATURE SOLDERING.** Thermal shock during soldering can be a major threat to ceramic devices, particularly chip capacitors and resistors. A device is said to be shocked when temperature increases or decreases too rapidly, and/or when temperature gradients ( $\Delta t$ ) are too great. To reduce the chance of thermal shock in wavesoldering, two thermal limits were defined. The first specifies that the rate of preheating should not exceed approximately 2°C per second, meaning that the chip - as measured by a thermocouple imbedded in the capacitor or resistor - should not experience a rise of more than 2°C per second. The second thermal limit states that the difference in temperature between the preheated component and the solder wave it encounters initially (in dual-wave systems) must not exceed approximately 100°C.

Burley, James (Hollis Automation Inc, Nashua, NH, USA). *Electronics* v 33 n 6 Apr 1987 p 23-33.

**085354 HOW TO ELIMINATE WAVESOLDERING DEFECTS.** The relationship between time and temperature in soldering ensures proper wetting and complete capillary rise in all plated through holes. However, the effect of time/temperature relationships on the creation and/or elimination of soldering defects is less understood. This paper discusses this problem and concludes that process-related solder defects can be eliminated and should not be accepted. The time/temperature relationship can be used as a tool for improving first pass yields through the wavesoldering system.

Down, William H. (Electrovert USA Corp, Arlington, TX, USA). *Electronics* v 33 n 6 Apr 1987 p 35-36.

**085355 FLUX SELECTION FOR PWB WAVESOLDERING.** The selection of a flux for wavesoldering is dependent upon the type of board, its use, economics, and whether or not cleaning is required (and if so, to what degree). Ideally, the least aggressive flux and solder at the highest possible speed should be used. Specific gravity of the flux must be maintained at prescribed levels. For foaming fluxes, the compressed air introduced must have a minimum moisture content. For spray fluxing applications, the solvent blend must be adjusted carefully and controlled to prevent clogging. Wavefluxing, another alternative to foam fluxing, is used primarily for high solids content applications, particularly for optimum through hole penetration. Soldering should take place at the lowest possible temperature consistent with flux activity and conveyor speed.

Anon. *Electronics* v 33 n 6 Apr 1987 p 37.

**085356 PROBLEM OF RESIDUAL FLUX.** Improper or inadequate cleaning of electronic assemblies leaves harmful flux residues containing both ionic and organic (non-ionic) material. To ensure that the results of all tests performed to find residual flux after soldering would be applicable to the widest possible range of solvents and fluxes, it was decided that rosin left on printed circuit boards (PC boards) would be measured after cleaning in a fluorocarbon-113/methanol blend, a 1,1, 1-trichloroethane/alcohol blend or a fluorocarbon-113 solvent. This procedure allows for accurate comparisons to be made concerning the flux/defluxer combination and aids in the accurate determination of amount of rosin residue so that the optimum cleaning cycle can be observed.

Archer, Wesley L. (Dow Chemical Co); Nalazek, Jeffrey J. *Assem Eng* v 30 n 12 Dec 1987 p 20-23.

**085357 DOD-STD-2000: THE ROAD TO COMPLIANCE, PART 2.** DOD-STD-2000 is an attempt to efficiently pull together the current soldering specifications of the Navy, Air Force, Army and Defense Logistics Agency into a simpler, more comprehensive standard. In this article, we will show how strict enforcement of DOD-2000 will constrain military suppliers of PCB assemblies. Specifically, we will discuss the standard's impact on machine soldering and what manufacturers can do to meet the standard's criteria.

Roy, Roland (Royer Manufacturing, Chelmsford, MA, USA); Grinovich, Ed; Worthington, Shari. *Circuits Manuf* v 27 n 9 Sep 1987 p 50, 53, 55-56.

**085358 NEW PHASE IN VAPOR PHASE.** Significant improvements in vapor phase soldering (VPS) equipment have affected both the cost and the viability of this assembly method. The past several years have seen reduced system and operating costs, higher production throughput, simplified operation and greater reliability. In response to increased competition, manufacturers have improved equipment designs and reduced prices accelerating the rate of VPS development. Today, inline VPS units come with belt widths up to 42 in. and can process at rates of 5 to 10 ft/min. Equipment manufacturers now offer a variety of VPS system designs, including small tabletop prototyping units, batch units for low volumes and inline systems for large production runs. Evolution of the VPS process and 15 years of field experience have produced VPS systems that more closely meet user needs.

Pignato, John (3M, St. Paul, MN, USA). *Circuits Manuf* v 27 n 9 Sep 1987 p 71-72, 74, 76.

**085359 TI SOLVES WICKING PROBLEM.** Soldering wicking can cause open solder joints when J-leaded devices are processed in a vapor-phase system. This article describes a quantitative method for analyzing the wicking problem and a new solder paste. The new paste achieves the delayed mobility by taking into advantage the alloying properties of tin and lead. The degree of reflow delay is also affected by prebaking the assemblies prior to reflow. 9 refs.

McLellan, R. Neil (Texas Instruments, Dallas, TX, USA); Schroen, Walter H. *Circuits Manuf* v 27 n 9 Sep 1987 p 78 and 85.

**085360 COMMON PROBLEMS WITH HOT AIR SOLDER LEVELING - PART 2.** This is the second part of a two-part article about common problems encountered during hot air solder leveling and recommended solutions. Part two describes problems caused during solder leveling. The following problems may be caused either during solder leveling or during other fabrication processes: short circuits or wicks (tails) on the PWB, bridging, grainy solder on PWB, solder mask peeling, delamination, scratches or tape residue on PWB, solder on gold tips and gold peeling from gold tips.

Fischer, Ivo Jr. (Voss Electronic Inc, Santa Ana, CA, USA). *Electronics* v 33 n 7 May 1987 p 22.

**085361 WAVE SOLDERING SMDs.** Although surface mounted devices were never designed to be wave

soldered, many users are successfully using this method of attachment. The component joint areas must be solder wettable. If they are not, the user will encounter failures for which the soldering process cannot be blamed. The author examines the behavior of liquid wave solder as it meets the SMD. Joint formation and the prevention of solder bridging are also examined. 1 ref.

Schouten, Gert. *Electron Prod (London)* v 16 n 11 Nov-Dec 1987 p 21, 23.

**085362 SOLDERING WITHOUT CLEANING.** The steady advance of Surface Mount Technology (SMT) has spurred development of fluxes that leave minimum residues after soldering. A range of synthetic-based soldering products is presented whose soldering residues can be regarded as safe to ISO and other specified requirements. These are already widely used internationally. Although they are not yet recognized as fully acceptable for US military requirements, moves are afoot to have them seriously considered for US defense contract work. Meanwhile, they are used extensively in consumer and professional electronics production. Various types of fluxes, resin, organic and inorganic, are reviewed, clarified by ingredients, and flux form (liquid, solid, paste) and their typical properties are listed.

**085363 SURFACE PREPARATION ENSURES UV SOLDER MASK ADHESION.** Since their introduction in the early 1970s, UV-curable solder masks have shown major growth in replacing conventional, thermally cured solder masks. While conventional solder masks, such as the two-part epoxy, still enjoy considerable popularity among today's board manufacturers, UV-curable masks have been gaining acceptance, especially from the high-volume board shops. About one-third of the commercial solder masks used today are believed to be UV-curable systems, and continued future growth is expected. The success of UV-curable solder-mask adhesion is dependent upon consistently good surface preparation.

Wang, Alan E. (London Chemical Co, Bensenville, IL, USA). *Electron Packag Prod* v 27 n 2 Feb 1987 p 123-124.

**085364 HOT TINNING AND SOLDERABILITY.** Tinning, or hot tinning as it is sometimes known, has been the mainstay of the assembly house when poor solderability of component leads causes defective solder joints on the shop floor. Some aggressive flux, a solder pot, and hands to dip the parts and later clean them, are the only tools required. In the last few years the process has moved to the manufacturing side of the industry, and tinning is slowly becoming the preferred method for assuring solderability when the parts are made and for securing a long solderable life.

**085365 ANALYTICAL MODEL FOR LASER REFLOW SOLDERING OF AN ELECTRONIC COMPONENT.** An analytical model for laser reflow soldering of a thick-film ignition module is presented in this paper. The analytical model is used to better understand the effect of process variables on soldering. The process variables investigated include beam power, beam ontime, beam spot diameter, preheat temperature, and specimen materials and configurations. Conclusions drawn from the model analysis are compared against experimental results for verification. The model was found useful in understanding the process and developing an optimum soldering schedule for manufacturing. (Author abstract) 14 refs.

**085366 CHOOSING A SOLDER MASK FOR HIGH DENSITY PWB'S.** Screen printing will continue to be the method selected for masking large lot, low- to moder-

ate-density panels because of its costs advantages compared to photoimageable systems. However, photoimageable solder masks will account for an increasing share of the solder mask market because of increasing circuit and hole densities; surface mount technology (SMT) penetration; and use of just in time (JIT) inventory and supply programs; and increasing emphasis on quality aesthetics. This paper discusses the subjects of PWB density versus process latitude, SMT and yield improvement, JIT inventory and supply programs, board quality and aesthetics.

**085367 HOW TO HANDLE, APPLY DRY FILM SOLDER MASKS.** This paper describes the handling methods and application of dry film solder mask in Automata Inc., Reston, VA. The subjects of discussion include: shelf life, panel processing (cleaning, drying, laminating, etc.) - critical handling and process control.

O'Loughlin, Michael (ELECTRONICS, Libertyville, IL, USA). *Electronics* v 33 n 14 Sep 1987 p 21-23.

**085368 PRINTED CIRCUIT BOARDS FOR INDUSTRY.** This paper gives an outline of modern printed circuit board (PCB) production, introduces some production facilities in UK and describes various applications of tin and tin-lead in PCB production.

Karpel, S. *Tin Its Uses* n 155 1988 p 5-8.

**085369 HOW TO IMPROVE PWB WAVESOLDERING.** High speed printed wiring board wavesoldering operations require careful consideration of four basic elements: base metals, solder alloys, heating profiles, and fluxes. This paper discusses the ways to optimize these elements in order to improve the soldering performance of a board.

Harris, Aaron (Litton Systems Inc, Des Plaines, IL, USA). *Electron Manuf* v 33 n 18 Dec 1987 p 19-21.

**085370 LAMP IR SOLDERING.** The T3 lamp used for solder fusing has a low-mass tungsten filament element sealed within a quartz envelope filled with inert gas. The lamps are designed to work for 5000 hr at 2500°K. In SMT applications, lamp life is usually 20,000 hr at temperatures of 1500°K. The T3 radiant emitter provides fast and efficient product heating. A rapid-response capability is the lamp's greatest advantage. Within 1 sec of a voltage change, the lamp is at 90% of its new equilibrium temperature. This rapid response makes the lamp system ideally suited for closed-loop temperature control. Another benefit of the lamp system is its ability to change profile temperatures rapidly.

Cox, Norman R. (Research Inc, Minneapolis, MN, USA). *Circuits Manuf* v 28 n 5 May 1988 p 43-44.

**085371 PANEL/CONVECTION IR REFLOW.** Convection/IR is a system specifically developed for reflow of SMT board assemblies. Heating of the assembly can be done in a controlled and uniform manner, regardless of size, color or density of the work, and without the added expense of an inert atmosphere. In light of the inherent characteristics of lamp versus convection/IR and the application at hand, careful consideration should be given to the IR technology used. Board composition in terms of overall mass, size, component density and makeup, solder and substrate material may or may not interact with the type of IR employed with regard to wave length, absorptivity, and presence or lack of convection heating. Machines should be considered and compared from a hands-on standpoint, and their results should be assessed in terms of uniformity of heating, control of heat rate, throughput, ease of setup, facilities required and repeatability.

Zarrow, Phil (Vitronics Corp, Newmarket, NH, USA). *Circuits Manuf* v 28 n 5 May 1988 p 47, 49.

**085372 FORCED CONVECTION IR REFLOW.** The various types of reflow are described. Two major problems with conventional panel systems are examined. It is shown that forced air improves IR reflow system performance in two distinct ways. The technology minimizes temperature gradients between components of differing thermal mass by blowing fresh air at precisely controlled temperatures across the board during ramp-up stage. By setting air temperatures just below the hottest spot on the board, the cool regions of the board can be heated without overheating the hotter regions. This air flow continues to moderate temperature gradients during reflow where maintaining equilibrium is critical. The second advantage of forced-air convection radiant heating is the minimization of across-panel temperature gradients under high throughput conditions.

**085373 SMT-LEITERPLATTEN-BAUGRUPPEN. ENTWURF - BESTUECKEN - LOETTECHNIKEN - LOESTOPMASKEN.** [SMD Printed-Circuit Board Modules. Design - Assembly - Soldering Systems - Solder Resist Masks]. This article is intended to help the PCB designer and artist create the type of PCB design which makes the production of the PCBs as simple as the circumstances allow, enables assembly and soldering with high ultimate efficiency, allows the PCBs to be inspected and, in the event of defective components, permits simple repair of the module. (Author abstract) In German.

Weinhold, M. *F&M Feinwerktech Messtech* v 96 n 5 May 1988 p 197-200.

**085374 PRAXIS DER DAMPFPHASEN-REFLOW-LOETTECHNIK.** [Vapour-Phase Reflow Soldering in Practice]. The special geometries of SMD components and their temperature sensitivity have resulted in both the modification of existing soldering systems and the introduction of new reflow soldering techniques. This article deals with vapour-phase soldering and focuses on a selection of systems in practical application. (Author abstract) In German.

Panzer, Birger. *F&M Feinwerktech Messtech* v 96 n 5 May 1988 p 201-204.

**085375 WELLENLOETEN VON SMDs.** [Wavesoldering of SMDs]. Use of SMDs (surface-mounted devices) entails applying the solder as paste prior to soldering before the component is mounted. The connection is then made by reflow soldering. SMDs are now also being bonded on the bottom side of PCBs and soldered in a solderwave. Basically speaking, SMDs are not especially suited for wavesoldering, so it is necessary to apply the measures described in the article in order to improve the soldering. (Author abstract) In German. 2 refs.

Schouten, G. *F&M Feinwerktech Messtech* v 96 n 5 May 1988 p 205-207.

**085376 STATISTICAL VARIATIONS IN SM COMPONENT SOLDERABILITY TESTING.** The reduced size of many military and consumer electronic systems has brought surface mount technology to the forefront of electronic packaging. SMT demands superior joint quality to ensure adequate reliability, but unfortunately, SMT solder joints are prone to low cycle fatigue failures caused by substrate and component thermal coefficient of expansion (TCE) differences. Because of this, component and substrate solderability must be tested by both the vendor and component user to achieve the goal of high reliability. Agreement on test conditions and test results is essential. This study quantitatively assesses the impact of varying certain test conditions on the solderability test results of surface mount components (SMCs). The variables include flux activity level, steam aging chamber design, and steam aging time. These particular variables were chosen because they often are sources of conflict between component vendors and users when solderability test results do not agree. 7 refs.

Evans, John W. (Unisys Corp, Greenbelt, MD, USA). *Surf Mount Technol* v 1 n 5 Oct 1987 p 21-24.

**085377 HOW PRETINNING, TESTING HELP IMPROVE SOLDERABILITY OF SURFACE MOUNT COMPONENTS.** The purpose of pretinning parts prior to use is to improve solderability. In order to achieve the best results, parts should be pretinned prior to storage. This will increase shelf life and improve solderability by providing a fused layer of tin/lead coating. It is even more beneficial to perform solderability testing prior to acceptance and pretinning. Without this additional step, vendor-related problems may be masked or otherwise go unnoticed if a strong flux is used for pretinning.

Tiehl, Rena E. (TRW Operations & Support Group, Redondo Beach, CA, USA). *Surf Mount Technol* v 1 n 5 Oct 1987 p 31-36.

**085378 HOW A DEFLUXING SOLVENT HELPED INCREASE PRODUCT EFFICIENCY.** Finding the right combination of production parameters and defluxing solvent has increased PCB production efficiency noticeably. However, additional benefits are being realized as higher quality boards and computers are delivered to the market. On the assembly floor, the new defluxing solvent has eliminated the buildup of contaminants on the heating elements of the defluxing unit and in the still. Cleaning is now determined by the amount of rosin suspended in solution instead of the fear of caked rosin buildup on the heating elements. The improved solvent stability over previous solvents also has resulted in a lower volume of waste requiring disposal - generation of waste has been reduced from about 55 gallons per month to 10.

Humphrey, Joe (Harris Corp, Ft. Lauderdale, FL, USA). *Electron Manuf* v 34 n 7 Jul 1988 p 8-9.

**085379 UNDERSTANDING AND CONTROLS NECESSARY FOR WAVE SOLDERING RELIABILITY - PART 1.** Whether soldering by hand with a soldering iron and flux-cored wire solder, or with automated soldering machines, there are four important considerations requiring thorough understanding and tight control: 1.) Solderability, 2.) Flux, 3.) Solder, and 4.) Heat. Every soldering application involves these four factors, all equally important in the process of completing reliably soldered assemblies. Circuit board metal surfaces, the type of plating, protective coatings, and layout should be selected with soldering in mind. Component lead solderability and placement on the PCB in a solderable configuration also determine the reliability of the soldered assembly. The choice of soldering flux is related directly to the solderability of the metal surfaces. The solder alloy selected and the level of purity determine the speed of soldering. This paper discusses the subjects of solderability, soldering flux and flux removal. Metal solderability chart and flux selection guide are included.

Bernier, Dennis F. (Litton Systems Inc, Des Plaines, IL, USA). *Electron Manuf* v 34 n 7 Jul 1988 p 10-13.

**085380 VAPOR PHASE SOLDERING BASICS.** Vapor phase mass reflow soldering (VPS) is a non-contact soldering process that takes place in a vapor-filled zone. This thermal transfer vapor is formed by heating a perfluorinated electronic liquid that boils at a temperature higher than the solder reflow temperature. The VPS technique uses condensation heating - the transfer of the latent heat of vaporization of the saturated vapor to circuit assemblies as the vapor condenses on these cooler surfaces. The VPS process has potential in certain cases for significant increases in circuit production over alternate soldering methods. It offers a high level of solder joint uniformity and reliability, even for densely packed, complex, high mass assemblies and odd geometries. These benefits are due to the characteristics of perfluorocarbon liquids and the efficiency of heat transfer obtained from a condensing vapor.

Ruffing, John (3M, St. Paul, MN, USA). *Electron Manuf* v 34 n 7 Jul 1988 p 20-21.

**085381 SOLDERABILITY AND SURFACE MOUNTING.** In the last decade through-hole mounting to printed wiring boards has matured and people now have the tools to diagnose and correct any solderability

problems which might arise. Such is not the case with surface mount soldering technology. In surface mount the connections are smaller and are often hidden from view. Therefore when a solderability problem occurs it may never be known until the assembly fails. The solution to the situation is to understand the nature of the problems and provide assurance that they will not occur during assembly soldering. This paper details the types of solderability problems unique to surface mounting. Examples of these problems are shown and discussed with reference to solder joint life. The second part of the paper discusses the solderability testing of surface mount devices and printed wiring boards intended for surface mounting. This discussion concentrates on the new quantitative solderability test methods being developed for leadless devices and printed wiring boards. New solderability criteria have been defined which reflect the unique problems associated with surface mounting. (Edited author abstract). 7 refs.

DeVore, J.A. (GE, Syracuse, NY, USA). *Circuit World* v 14 n 4 Jul 1988 p 37-41.

**085382 KNOW THY PROCESS.** The author shows how automated process information systems can play a big role in moving the wave soldering process out of the realm of black magic and into the domain of methodical, scientific management. Such systems can provide a comprehensive view, in useful terms of what is really going on in this complex process. By watching what is happening in the wave soldering process, you can act on problems before they become serious, while continually improving performance. These systems allow a manufacturer to run each board type according to a unique, optimized soldering recipe to track down the resource of problems, to improve soldering results based on experience, to improve new product introductions, to increase operator involvement and to apply statistical process control techniques to soldering operations. Elements of a process information system are discussed.

Picker, Dennis (Fidelis Group Inc, Newton, MA, USA). *Circuits Manuf* v 28 n 8 Aug 1988 p 4p.

**085383 SURFACE MOUNT PRODUCIBILITY AND RELIABILITY.** A design perspective on common SMT assembly concerns is presented. It is pointed out that as in the case of printed circuitry, components must be specified for reliable applications concerning SMT. Emphasis in this paper is on solderability. Component and printed circuit solderability, in conjunction with the solder medium and process, is all there is to a solder joint; if one of these elements is questionable, so is the solder joint itself.

Moon, Earl (Proof of Design, San Jose, CA, USA). *Printed Circuit Des* v 5 n 8 Aug 1988 p 30-35.

**085384 PRINTED CIRCUIT BOARD CLEANING AGENTS AND SOLDERING FLUXES: CFC ALTERNATIVES.** The selection of a flux for printed circuit soldering and a possible cleaning material or method traditionally have been dependent on a number of factors. However, selection considerations increasingly are being influenced by concerns over depletion of the earth's ozone layer by chlorofluorocarbons (CFC's). In electronic manufacturing, CFC's are widely used for solvent cleaning to remove soldering flux residues for components and PCB's after wave soldering. Research efforts already are underway to find alternatives to soldering with rosin flux and cleaning with CFC-based solvents. This paper explains what is a CFC and discusses the concerns about the ozone, the conservation measures and CFC alternatives, among them chlorinated solvents, alkaline saponifiers, emulsifiers and water soluble fluxes.

Bernier, Dennis (Litton Systems Inc, Des Plaines, IL, USA). *Electron Manuf* v 34 n 8 Aug 1988 p 29-31.

**085385 UNDERSTANDING THE CONTROLS NECESSARY FOR WAVE SOLDERING RELIABILITY - PART 2.** Soldering is the most economical way to make reliable electrical connections. However, failure of electronic equipment may result in defective solder joints. To combat solder joint problems, the user of soldering material should become familiar with the basic requirements for producing the necessary skills in using the proper solder, flux, and solder equipment. There are four important considerations to take into account for proper soldering techniques: 1) solderability, 2) flux, 3) solder, and 4) heat. Part 2 of this feature will discuss solder alloys and impurities, heat, and computer controls.

Bernier, Dennis F. (Litton Systems Inc, Des Plaines, IL, USA). *Electron Manuf* v 34 n 8 Aug 1988 p 35-36.

**085386 AUTOMATION OF SOLDER JOINT INSPECTION PROCEDURES UTILIZING LASER INDUCED INFRARED.** Automation of solder-joint inspection by means of laser-induced infrared radiation is investigated. A focused laser beam is used to apply an intense, short-duration heat pulse to the surface of the solder joint to be evaluated. This heat flows freely into the metallic interior of the joint by conduction while the surface of the joint emits radiation. The temperature rise on the surface of the joint is monitored by an infrared detection system, which also monitors the cooling process following the laser pulse. This infrared signature is used to detect defective joints. The capabilities of the system and the advantages of automated inspection are discussed. 2 refs.

## Stresses

**085388 STRESS AND DEFLECTION ANALYSIS OF PARTIALLY ROUTED PANELS FOR DEPA-NELIZATION.** Analytic studies of deflection and stress in partially routed panels using the finite-element method are discussed. Emphasis is placed on the effects of partial routing on the assembly processes for surface-mount printed circuit boards. To test the validity of the finite-element results, the overall deflection profile of a partially routed panel was measured. The calculated deflection profile agreed with the experimental results. Two different tab configurations have been designed, and four connecting tab widths have been analyzed for each design. The results indicate that panels dimensions could be partially routed without causing material failure or compromising solder-joint quality. 20 refs.

**Testing** See Also AUTOMATIC TESTING; INTEGRATED CIRCUIT TESTING; INTEGRATED CIRCUITS, VLSI—Testing; TELECOMMUNICATION EQUIPMENT—Testing.

**085390 ROLE OF INTERFACE BUSES IN PRINTED WIRING BOARD TESTING.** Printed wiring board testing has become increasingly complex as the number of instruments required in the test environment has increased, and costs of both hardware and software have changed over time. Adding to this complexity is concern about networking, that is, ensuring that all the instruments in the test environment are communicating with each other. The interface bus and associated hardware and software products are fundamental to this communication. A combination of hardware and software may be used to provide the required interfaces for a particular board testing application. This paper discusses various interface solutions and the concept of a 'virtual instrument' (VI) to create test equipment in software or to control real test equipment. A VI is similar in function to a physical instrument. However, it is created out of software, and may be made up of other virtual or real instruments. Virtual instruments are designed to take the place of dedicated hardware by tailoring general purpose hardware into specialized test functions.

**085398 LOW VOLTAGE INSULATION RESISTANCE MEASUREMENT OF PRINTED CIRCUITS AND ITS IMPLICATIONS.** The use of surface insulation resistance testing has been restricted to QC laboratory applications. The extension of this technique to modern electronics and, in particular, to contamination control of SMAs has forced the development of new methods of SIR measurement. These have revealed that existing standards are rapidly becoming obsolete because the premises on which they are founded are no longer valid. Even more alarming, it is revealed that we are rapidly reaching, not only the limit of our knowledge in the field, but also the technical limits of existing standard materials used in industry today. This paper is a warning against too much complacency, as the risk of running into real problems, at all process stages, will become very pertinent within a few years. The technical content of this paper is based on about three years' study of the subject resulting in the measurement of SIR at about 10 v, as opposed to the traditional values of 100 and 500 V, which have been proved to be of little value with conductor spacings such as are usual on SMAs. (Author abstract) 15 refs.

Ellis, B.N. (Protonique SA, Romanel-sur-Lausanne, Switz). *Circuit World* v 14 n 2 Jan 1988 p 21-25.

**085399 FOR HIGHER YIELD: TEST OR INSPECT BARE PCB'S?** Test and inspection systems are more complementary than competitive. While there is some performance overlap, both have unique benefits. Electrical test is swift and has a favorable price/performance ratio; AOI provides real-time process control and detects flaws, invisible to test, that affect reliability.

Spitz, Leonard (Electronic Packaging & Production, Newton, MA, USA). *Electron Packag Prod* v 27 n 2 Feb 1987 p 96-98.

**085400 ESD FAILURES OF BOARD-MOUNTED DEVICES.** Electrostatic discharge (ESD) plagues the modern microelectronics industry and poses unique reliability problems due to failures on the production line, in the inspection department, at the stockroom, while in

transit or in the hands of customers. Such ESD threats are supposedly experienced only in isolated devices; that is, in devices which are not mounted on a printed circuit board (PCB). This presumption is incorrect. It is a myth that an ESD-sensitive component cannot be damaged once installed on a circuit board. Analysis and simulated experiment indicate that mounted devices are more vulnerable to ESD than are unmounted devices. 12 refs.

Neelakantaswamy, Perambur S. (RIT Research Corp, Rochester, NY, USA); Turkman, Rennen I. *Electron Packag Prod* v 27 n 2 Feb 1987 p 132-134.

**085401 SOLUTIONS BEGIN TO SURFACE FOR LINKING BOARD DESIGN AND TEST.** Although many tools have been developed to automate the efforts of design engineers and test engineers, little has been done to make design tools and test tools compatible. And until recently, there hasn't been a big push to force design and test to communicate and make use of each other's efforts. This is somewhat understandable, since the design engineering department and the test engineering department are separate entities in most companies. This article shows how many companies are finding ways to link design and test tools, including recruiting the services of third-party vendors. The main topics are linking CAE to ATE, compatibility of test and design, how third-party links assist test, and CEA/ATE standardization.

DeSena, Art (ADS Associates, USA). *Comput Des* v 27 n 5 Mar 1 1988 p 34-39.

**085402 FLEXIBLE PCB TEST WORK-CELL.** Flexible robotic-based work-cells are considered that design and implement flexible PCB test systems to reduce human handling and thereby improve the yield of assemblies. In addition to improving quality, the PCB test work-cell is justified by increasingly complex test procedures that can best be driven and monitored through software integrated with the work-cell. The robot can also service multiple test sets, thereby eliminating idle labor time and increasing productivity.

Pearce, Bill (Intellex Inc, Corvallis, OR, USA). *Circuits Manuf* v 28 n 2 Feb 1988 p 37-38.

**085403 NEW STRATEGIES FOR BUS-STRUCTURED PCB TESTING.** Bus timing emulation is widely used for the production testing of bus-structured printed circuit boards. However, with the ongoing advance of bus-structured technology, continued successful use of the technique will require new facilities for, and approaches to, test hardware, fixturing and design for testability. The bus timing emulation technique continues to be used successfully for testing state-of-the-art bus-structured boards. The BTE test hardware has evolved rapidly to keep pace with advancing bus-structured technology. In order to achieve maximum test efficiency it is necessary for careful consideration to be given to fixturing and PCB design for testability. (Edited author abstract)

Hay, Malcolm J. (Zehntel Performance Systems). *Comput Aided Eng J* v 5 n 1 Feb 1988 p 29-32.

**085404 FIXTURING FOR ATE. SHIFTING INTO HIGH GEAR FOR SMT.** The advent of mount technology (SMT), drastically has changed ATE fixturing. Probing point accuracy, repeatability and 50-mil centers must be addressed by everyone involved with fixture design. Selection of the probe is one of the first considerations facing the fixture designer. High-density boards require probes with excellent pointing accuracies. Design for testability (DFT), functional testing and probing accuracy are discussed.

Anon. *Eval Eng* v 27 n 4 Apr 1988 8p.

**085405 FUNCTIONAL BOARD TEST HYBRID DIAGNOSTICS. THE EVOLUTION AND ADVENT OF ANALOG SIGNATURE ANALYSIS. PART 2.** Hybrid functional testing is composed of two distinct processes. Hybrid go, no-go testing means that the functional ATE provides a cycle of mixed-signal stimulus and predicted response. If at least one significant deviation from either the predicted (simulated) or learned response

set is detected, then the functional ATE proceeds to enter the second board test process, hybrid diagnostics the fault isolation phase. For descriptive purposes, the hardware and software implementation solution for analog functional hybrid diagnostics is presented using the Schlumberger ATE (FACTRON) Series 700 tester line.

**085406 BARE BOARD TEST METHODS FOR HIGH DENSITY BOARD DESIGNS - PART 1.** This is the first of a two-part article describing bare board testing alternatives. The first part discusses the bed-of-nails method, high density fixturing problems, universal grid systems, and the moving probe method. (Edited author abstract)

Conti, Joseph (Kollmorgen Corp, Melville, NY, USA). *Electronics* v 33 n 14 Sep 1987 p 31-32.

**085407 BARE BOARD TEST METHODS FOR HIGH DENSITY BOARD DESIGNS - PART 2.** This is the second part of a two-part feature about bare board testing. This part describes use of the moving probe method, fixtures vs. probes, and the future of bare board testing.

Conti, Joseph (Kollmorgen Corp, Melville, NY, USA). *Electronics* v 33 n 16 Oct 1987 p 39.

**085408 USING PERFLUORINATED ELECTRONIC LIQUIDS FOR COMPONENT TESTING.** Perfluorinated electronic liquids - high dielectric fluids with unusual physical characteristics - are used for several distinctly different applications in the electronic industry. This class of liquids is chemically inert, colorless, non-toxic, nonflammable, and compatible with printed wiring board and component materials. As a replacement for air in electronic testing, perfluorinated electronic liquids improve the ability to control individual device temperatures and can reduce the time required for testing procedures. This paper gives examples of testing procedures that make use of these liquids. Among these procedures there are ceramic crack test, thermal shock test, liquid burn-in testing and environmental testing.

**085409 HOW TO TEST FLEXURAL FATIGUE, ENDURANCE, DUCTILITY OF FLEXIBLE PWB'S.** Various test methods are used to test the physical and mechanical characteristics of flexible printed wiring boards during fabrication. The choice of test method used should be based upon the substrate type and the particular characteristic to be tested. This article examines the substrate materials used and details several flexural endurance and fatigue tests recommended by the Institute for Interconnecting and Packaging Electronic Circuits (IPC), Lincolnwood, Ill.

Moosman, Kari (Electronic Manufacturing, Libertyville, IL, USA). *Electron Manuf* v 33 n 18 Dec 1987 p 13-14.

**085410 OPTIMIZING THE IN-CIRCUIT TEST PROCESS.** This paper describes a mathematical model of the in-circuit test process and the effects of the following 3 parameters: 1) Yield (from assembly): percentage of boards that pass the first time that they are tested; 2) Test time: average test time per board; and 3) Efficiency (shift): percentage of total shift time actually available for testing boards. Fractors that influence the parameters are also discussed. These are: assembly process design, test process design, physical PCB design, electrical PCB design and test design.

Curtis, Steve (Telex Corp, Raleigh, NC, USA); Douglas, Phil. *Electron Manuf* v 34 n 6 Jun 1988 p 11-13.

**085411 TESTING PHILOSOPHY FOR ZERO DEFECTS.** A philosophy for improving the yield problem is to verify the part is correct and properly oriented for installation. A complete test is not necessary because the

part has been through receiving inspection. This philosophy redefines the function of test. Instead of identifying or detecting faults after the manufacturing process, the emphasis is on preventing defects from entering the process. The philosophy is then based on eliminating defects rather than detection and rework to produce quality finished goods. With in-process test and automation, the concept of zero-defects becomes truly practical. Benefits of zero-defect approach are discussed.

Shemeta, E.H. (Boeing Electronics Co, Seattle, WA, USA). *Electron Manuf* v 34 n 5 May 1988 p 20-24.

**085412 TEST STRATEGY DEVELOPMENT: A BROAD APPROACH.** Current manufacturing industry trends significantly impact new product test strategies, and today's business environment requires a broad selection perspective. The paper discusses types of test systems, forces affecting test strategy, general test philosophies and product test strategy selection.

Martin, Mike (Tektronix Inc, Vancouver, WA, USA). *Electron Manuf* v 34 n 5 May 1988 p 25-28.

**085413 FEATURES TO CONSIDER WHEN CHOOSING A BURN-IN TEST OVEN.** When considering the purchase of a chamber for burn-in test applications, the two most important factors to weigh are the value of the workload and the value of the oven. It is not unusual for a workload to be worth \$250,000 or more. Thus, the cost of the workload may far exceed the combined cost of the burn-in chamber and the necessary interior fixturing. In fact, the chamber itself often is the least expensive element in a burn-in test system. Accordingly, only a first quality chamber should be considered, because in burn-in testing, a quality chamber is a safe chamber. This paper discusses the following subjects: burn-in test procedures, adjusting heat levels over-temperature protection of test chamber and oven design.

Scheppe, William (General Signal, Blue Island, IL, USA.). *Electron Manuf* v 34 n 3 Mar 1988 p 37-38.

**085414 COMPUTER INTEGRATED PC BOARD TEST & REPAIR.** Printed circuit board test and rework is an area which, like design, machine insertion, flexible assembly, wave solder, and the other processes involved in the production of pc boards, must be incorporated under the umbrella of computer integrated manufacturing (CIM) to reduce costs and improve quality and productivity. This article discusses how printed circuit board production test and repair can effectively be made part of an overall computer integrated manufacturing system.

Saunders, Glenn (CIMM Inc). *Assem Eng* v 31 n 5 May 1988 p 42-46.

**085415 QUEST FOR TEST.** The author reports on one development in bare board surface mount technology testing - a double-sided universal grid tester. She also discusses the importance of fixturing in the testing of increasingly dense circuitry on SMT boards and the use of CAD data download capability for designing fixtures and creating test programs.

Abrams, Alice C. (Circuits Manufacturing, San Francisco, CA, USA). *Circuits Manuf* v 28 n 3 Mar 1988 4p.

**085416 INTERFACE BRINGS STANDARDIZED DFT CLOSER TO REALITY.** A specification for a four-wire serial interface to incorporate boundary-scan cells for standard ICs and application-specific ICs is being finalized by the Joint Test Action Group (JTAG), an international ad hoc group of companies promoting standardization of design-for-testability techniques. The interface will enhance testability of printed circuit board assemblies and can virtually eliminate the need for bed-of-nails fixtures, especially critical when boards are designed using surface-mount components. A key feature of the JTAG 2.0 standard is a four-pin implementation with a clock, a single-mode input and serial I/O lines. It also has a small state machine to decode the mode input and generate control and clock signals, and it includes

serial path shifts for instructions or data. Multiple parallel data paths are available, including a bypass path and a boundary-scan path.

DeSena, Art (ADS Associates). *Comput Des* v 27 n 10 May 15 1988 p 104-105.

**085417 IDENTIFYING ISOLATION SHORTS DURING BARE-BOARD TESTING.** Isolation shorts are defects in the etched circuit traces or board composite or merely surface contaminants that become evident only when relatively high voltage is applied between traces. This article discusses the types of isolation shorts prevalent in PC board manufacture and specific steps recommended to test and identify these defects. The main topics are oxide whiskers, voltage arc-over and under etching, surface contamination, surface moisture, inner ionic contamination plus moisture, and recommended testing procedures. 3 refs.

Leech, Bill (Program Data Inc, Irvine, CA, USA). *Eval Eng* v 27 n 6 Jun 1988 p 136, 138.

**085418 BRINGING TEST ON BOARD.** Nodal access has become the most critical issue in testing surface mount boards. To overcome this potential problem, Texas Instruments uses a test strategy that provides in-circuit testing for surface mount boards with a 100-mil gap between components and 50-mil gap between components and 50 mil between component pad centers. This strategy involves an innovative land pattern design and a tightly controlled board manufacturing process. Manufacturing faults form the largest class of loaded board faults. Catching these faults is the main feature of in-circuit test because it isolates them less expensively than other test methods, such as functional or systems test. In-circuit test provides quick feedback to correct process faults before factory yields drop too low.

Keagy, R.A. (Texas Instruments, Dallas, TX, USA). *Circuits Manuf* v 28 n 6 Jun 1988 p 85-89.

**085419 LEITERPLATTEN-PRUEFUNG MIT MULTI-MODE-TESTER.** [Printed-Circuit Board Inspection with a Multimode Tester]. For many companies quality is the topmost priority. In order to be able to maintain the desired quality level for VME bus boards in large batches as well, the manufacturer Eltec decided at the end of 1986 in favor of using a multimode tester. The arguments in support of the company's decision are explained. (Edited author abstract). In German.

**085420 CONTROLLED ELECTROMIGRATION FOR FIELD FAILURE ACCELERATION.** A simple test for stressing specific areas of an assembly has been developed, using threshold values for the parameters studied that are based on understanding of the electromigration failure mechanism. This test can be applied to a functional system or component, and a life expectancy can be predicted. Incompatible components can be eliminated from the system or their surfaces prepared in such a manner as to prevent premature demise. This type of testing is well-suited to printed-circuit-board platings, component platings, and final assembly cleaning. With controlled electromigration the best possible process can be determined for coating the exposed metal surfaces so that maximum reliability is achieved. 8 refs.

## Thermal Expansion

**085423 T300 GRAPHITE CORE PRINTED WIRING BOARD: PREDICTING THE COEFFICIENT OF THERMAL EXPANSION.** Materials with low thermal expansion rates are being used in printed wiring boards (PWBs) to obtain a thermal expansion factor compatible with that of surface mounted leadless ceramic chip carriers (LCCCs), thus improving solder joint survivability and reliability. Boeing Electronics Company (BEC) selected T300 graphite, a constraining core material, as its baseline in establishing methodology for predicting and then measuring coefficient of thermal expansion (CTE). Predicted results from the Interactive Composite Analysis Program (INCAP) were compared with CTE measurements derived from a relatively new strain gage technique. (Author abstract)

**085429 MAGNETIC PRINTER FOR NEWSPAPER CTS.** This paper describes a magnetic printer which was developed as a proofing printer for newspaper CTS (computerized type-setting system). In order to produce a number of copies of the proof efficiently, this printer is intended to have copying function. In recording latent image, the recording drum is rotated at high speed of 4,000 r.p.m. A newly devised multiple-channel head is employed in the printer. The track width of the preceding channels are wider than those of the succeeding channels. The latent images recorded by the preceding channels are sequentially overlapped by the succeeding channels. The recording resolution of 454 dots per inch was achieved. In this paper the overview of the printer structure and operation is described, and the detail of the multiple channel head is discussed. (Edited author abstract) 3 refs.

**085430 MAGNETICALLY BIASED DEVELOPMENT OF MAGNETOGRAPHIC IMAGES.** The effect of magnetic bias fields on magnetographic development is studied. An analytical model of image field and associated force on toner particles is modified to incorporate bias fields of either direct or reverse polarity with respect to the dots magnetization. Using simple series expansions derived from the model, the main mechanisms of biased development are first identified. Based on the full model, 3-D computer simulations of the particles equilibrium on the imaged media, while exposed to bias fields of various intensity and polarity, are then provided and shown to reproduce quite reliably the real observed behavior. (Author abstract) 5 refs.

Eltgen, Jean-Jacques P. (Bull Peripheriques, Belfort, Fr). *IEEE Trans Magn* v MAG-23 n 5 Sep 1987, INTERMAG '87: Int Magn Conf, Tokyo, Jpn, Apr 14-17 1987 p 2892-2894.

**085431 VERY HIGH SPEED 450 PAGES-PER-MINUTE EXPERIMENTAL MAGNETIC PRINTER.** Starting from the MP magnetographic technology an experimental research program has been conducted to assess the potential of the technology for extension to much higher speeds. The magnetic shunt of the MP drum media was found to be the most limiting factor to significant speed increase. Characterization of various experimental media, in terms of write time constant, permitted a new 'fast' drum structure. As a result, a full function 8½ inch-wide, experimental magnetic printer was built and tested up to speeds of 450 pages per minute. (Author abstract) 3 refs.

**Color** See Also CERAMIC PRODUCTS—Decoration; COMPUTER PERIPHERAL EQUIPMENT—Plotters; COMPUTER PERIPHERAL EQUIPMENT—Printers; GLASS—Decoration; MECHANICAL VARIABLES MEASUREMENT—Volumes.

**085432 COLOR PRINTING A BALANCING ACT AMONG PRICE, PERFORMANCE, AND PRINT QUALITY.** Six basic color-printing technologies are: pen and electrostatic plotters, thermal-transfer, ink-jet, serial dot-matrix, and electrophotographic (color laser) printers. The vector-oriented pen plotters are by far the most popular, largely because they are flexible. They 'write' with varied-color pens on various media and have a large base of existing software. However, raster-based competitive technologies are gaining ground by offering faster print speeds, superior text printing, and compatibility with the emerging world of digital imaging. Generating and mixing colors, including dye sublimation and dithering, are also discussed.

**085433 NEW MODEL OF DOT GAIN AND ITS APPLICATION TO A MULTILAYER COLOR PROOF.** The phenomenon of dot gain, whether physical or optical, has been studied greatly with regard to printed inks. Off-press proofs must reasonably simulate printing gain in order to be predictive. Since the halftone colors of many off-press proofs are in multiple layers, optical gain will be much different from printed inks. This paper develops a new approach to the phenomenon of optical dot gain and examines the effect of multiple layers on gain, including the effect of screen resolution. (Author abstract) 9 refs.

Huntsman, James R. (3M, St. Paul, MN, USA). *J Imaging Technol v 13 n 5 Oct 1987 p 136-145.*

**085434 EFFECT OF PICTORIAL CONTENT ON PREFERRED GRAY BALANCE IN FOUR-COLOR HALFTONE PROOFS.** The objective of this study was to measure the influence of pictorial content on preferred gray balance in four-color, halftone, off-press proofs. The effect was studied by preparing single-sheet Matchprint proofs of three pictorial images in which the exposures of yellow, magenta and cyan were varied to produce dot gains which were  $\pm 3\%$  from a center point value. These nine color variations of each image were visually examined by 20 observers using the method of paired comparisons. The visual preferences were compared with colorimetric measurements of typical areas in each sample. Dot gain differences of 3% from a neutral center point proof produced CIELAB Delta E values of 2-4 which were usually apparent in all eight samples of each subject. (Edited author abstract) 4 refs.

**085435 COLOUR-DISTANCE JUDGEMENT AND THE INFLUENCE OF THE BACKGROUND IN COLOUR REPRODUCTION.** The influence of the background in colour reproduction can be described in

colorimetric terms by the use of corrections to the colorimetric scaling factors. This leads to transformation formulae that describe the change of chromatic adaptation. The method leads to an improved reconciliation between the specification of colour-rendering properties in both colour photography and multicolour printing and the visual evaluation. (Edited author abstract) 16 refs.

**085436 B350 VIDEO-PROCESSING UNIT FOR COLOR PRINTERS.** While the Centronics interface is useful for printing images in a single color, there is still no widely used standard for expressing multicolor-image data. With the development of multicolor thermal printers, this has become an important issue: multicolor printing via a Centronics interface requires that each application program have a special-purpose color-printer driver. In fact, very few such driver programs have been written, limiting the utility of existing color-printer technology. (Author abstract)

Kitamura, Shozo; Takakuwa, Kiyoshi. *Mitsubishi Electr Adv v 42 Mar 1988 p 15-17.*

**085437 HIGH-SPEED THERMAL-CONTROL TECHNOLOGY FOR THERMAL COLOR PRINTERS.** Mitsubishi Electric has been studying the effect of the heating elements on each other in order to devise methods to limit temperatures by reducing the duration of the current pulses applied to those elements during printing and by modifying the structures, thermal capacities, and thermal-transfer efficiencies of the head.

Onishi, Masaru. *Mitsubishi Electr Adv v 42 Mar 1988 p 30-31.*

**085438 CONTINUOUS-TONE COLOR HARD COPY.** Color scanners capture images at far higher quality levels than today's color hard-copy systems can reproduce. As a result, hard copies do not adequately support high-performance color image processing, and their support of computer graphics and computer-aided design (CAD) systems is limited. But industry is responding to this challenge with new approaches. Foremost among these is continuous-tone hard copy, in which each pixel can be varied in density and hue. Several continuous-tone hard-copy technologies are available, each offering distinct strengths and weaknesses. It is not yet clear which technology will dominate, but users and system integrators will soon have access to high-performance continuous-tone hard-copy systems.

Seldon, Denise (Honeywell Test Instruments, Denver, CO, USA). *Inf Disp v 4 n 10 Oct 1988 p 14-16.*

**085439 BICMOS THERMAL HEAD INTELLIGENT DRIVER WITH DENSITY CONTROLLERS FOR FULL-TONE RENDITION PRINTERS.** A 3- $\mu$ m BiCMOS thermal head driver using pulsewidth modulation dealing with eight-bit density input data (256 gray levels) is described. Circuits composed of 64  $\times$  8-bit complex counters, which function as eight-line parallel 64-bit shift registers (shift mode) and as 64 counters which have eight bits (count mode) by alteration of their mutual connections according to the mode signals, have been developed. The complex counter controls the output pulse width according to the binary data and the clock intervals (minimum 100 ns). The shift registers can operate using a 20-MHz clock. The driver consists of about 4500 CMOS gates and 128 bipolar transistors in a 2.8-mm  $\times$  8.8-mm chip size. The breakdown voltage of the bipolar transistor  $BV_{cb0}$  is more than 35 V. The driver is especially suited for full-tone rendition printers. Applications of the driver include use in thermal print heads, LED print heads, and LCD print heads. 4 refs.

## Computer Aided Design

**085440 HUMAN FACTORS DESIGN INVESTIGATION OF A COMPUTERIZED LAYOUT SYSTEM OF TEXT-GRAPHIC TECHNICAL MATERIALS.** In converting task listings into multiple pages of documentation for job aids or training, the two major problems are deciding how much material should go on each page and how text and graphics should be laid out on the page. A questionnaire study was used to collect input from 14 human factors personnel in order to design algorithms for page splitting and page layout. From the rules or heuristics used for page splitting, an algorithm was devised that closely matched human page-splitting results. Layout of individual pages was automated with an algorithm based on the (significant) consensus among the subjects on questions of graphics positioning and label ordering. The two algorithms have been combined in a computer-aided design procedure that automatically pages task lists and lays out individual pages. (Author abstract). 7 Refs.

Sylla, Cheickna (Drexel Univ, Philadelphia, PA, USA); Drury, Colin G.; Babu, A.J.G. *Hum Factors v 30 n 3 Jun 1988 p 347-358.*

## Computer Applications

**085441 INK JET PRINTING PAYS OFF FIVE WAYS.** Computerized carton coding with an ink jet printing system has paid off handsomely in expected benefits as well as some unanticipated bonuses for the Water Systems Division of Goulds Pumps, Inc., Seneca Falls, N.Y. The system at Goulds Pumps reduces label stocks, selects proper coding data, saves on labor, cross-checks carton usage, and adapts easily to marking new products and special orders.

Feare, Tom. *Mod Mater Handl v 43 n 8 Jul 1988 p 74-75.*

## Control Systems

**085442 TECHNOLOGISCHE BEDINGUNGEN FÜR DIE BEDIENARME PRODUKTION IN DER POLYGRAFISCHEN INDUSTRIE DURCH FLEXIBLE VERKETTUNG.** [Technological Conditions for Untended Manufacturing in the Printing Industry by Flexible Linking]. Technological conditions for untended production in the metal working and printing industries are different. Before deciding on a possible linking of machines, it is necessary to check to specific coupling criteria. It is necessary to state the fundamental relations for the calculation of the required speeds and storage quantities for a loose linkage as well as indications as to the further work tasks. (Translated author abstract) In German. 5 refs.

Ruder, Rudolf. *Wiss Z Tech Univ Karl Marx Stadt v 29 n 3 1987 p 412-418.*

## Density

**085443 OPTIMUM DENSITY LEVELS FOR MULTILEVEL HALFTONE PRINTING.** New dot matrix printing technologies are offering the possibility of printing more than one density level at any picture element location. The selection of optimum intermediate density levels depends on the optimization criteria and halftoning algorithm. We have used a minimax graininess criterion in conjunction with an error diffusion (Floyd-Steinberg) halftoning algorithm. Under some practical simplifying assumptions, there is a known relationship between the standard deviation of the density fluctuations, the granularity, and the average density. (Edited author abstract) 7 refs.

**Electrostatic** See Also OFFICE EQUIPMENT; POWERS—Magnetic Properties.

**085444 ION FLOW CONTROL CHARACTERISTICS FOR HIGH QUALITY CONTINUOUS-TONE**

**PRINTING.** Ion flow control is investigated theoretically and experimentally in order to achieve a high quality continuous-tone electrostatic printing process. The behavior of ion flux controlled by a pair of aperture electrodes is clarified by an analysis using computer simulation of ion trajectories, paying particular attention to the diameter of the ion flux. An electric charge image is formed experimentally by controlling ion projection time and analyzed by SEM observation and by measurement of surface potential, revealing its change with ion projection time. Gray-scale printing characteristics are then clarified by measuring the optical densities of the image developed with toner; 64 levels of gray-scale image are obtained with resolutions of 8 dots  $\text{mm}^{-1}$  and 12 dots  $\text{mm}^{-1}$ , demonstrating the feasibility of this method for continuous-tone printing. (Author abstract) 9 refs.

**Equipment** See Also PHOTOGRAPHIC REPRODUCTION; PHOTOGRAPHIC REPRODUCTION—Analysis; PHOTOGRAPHIC REPRODUCTION—Electrostatic; PRINTING PLATES—Evaluation.

**085445 MATRIX-LINE PRINTING.** In matrix-line technology, 24 print hammers are arrayed horizontally on an 8-inch shuttle (wide-carriage designs use more print hammers and a wider shuttle). The hammers fire simultaneously, printing an entire horizontal line of dots with a single 1/3-inch sweep of the shuttle assembly. A simplified drawing shows the design's major components. The advantage of the hammer-bank design are discussed.

Hohnaker, Mark (Printronix Inc, Irvine, CA, USA). *Byte* v 12 n 10 Sep 1987 p 215-216.

## Health Hazards

**085446 PROBLEMS OF PREVENTION OF OCCUPATIONAL DISEASES IN THE PRINTING INDUSTRY.** Lead-induced intoxications are regarded as the major cause of occupational diseases in the printing industry. The second place is occupied by skin diseases, primarily of allergic origin, which are followed by stress-associated disorders of the neuromuscular system of hands. Regular registration of occupational diseases confirms the necessity of implementing a set of preventive recommendations aimed at the improvement of technological equipment and labor conditions in the printing industry along with the introduction of scientifically proved work and recreation regimens. (Author abstract) In Russian. 4 refs.

Anan'ev, B.V. *Gig Tr Prof Zabol* n 5 May 1988 p 33-36.

## Heat Transfer

**085447 THERMAL-TRANSFER TECHNOLOGY COMES OF AGE.** Thermal-transfer printing can be described as a non-impact printing technology that uses thermal energy to transfer ink from an inked coated substrate to a receptor sheet. The ink transfer is caused not by the impact of the printing element to the ribbon, but by the heating up of elements on the print head to melt the ink on to the paper. Of the many different thermal-transfer printing devices that have been released or are under development, almost all require a unique ink formulation. Highly specialized ink making, coating, and slitting equipment is necessary to produce consistently high-quality monochrome and multicolored ribbons. Various considerations dictate the thickness of ribbon chosen for a particular application: (1) energy requirements to transfer the ink; (2) a preference for a particular length of ribbon; and (3) cost considerations.

O'Leary, John W. (Int Imaging Materials Inc, Tonawanda, NY, USA). *Inf Disp* v 3 n 5 May 1987 p 23-25.

**Laser Applications** See Also COMPUTER PERIPHERAL EQUIPMENT—Printers.

**085448 OPTICAL SCANNER DESIGN LEADS TO COMMERCIAL LASER PRINTER SUCCESS.** The

scanning optical systems in recent laser-printer models follow a common set of principles. A combination of one or two lenses (known as f $\theta$ -DEC) provides an f $\theta$  characteristic combined with deflection error compensation (DEC). Key elements of the scanning systems include a polygonal mirror scanner and a toric lens. To compensate deflection errors the authors developed a system of the so-called conjugate type, which has a high compensation ability. 4 refs.

**085450 IMPACT OF ORTHONAPHTHOQUINONE DIASIDE PHOTOLYSIS ON COPYISTS' HEALTH STATUS.** Deviation from the standard prothrombin time was detected in copyists. Correlation of the blood coagulation system variations with photolysis products' impact was experimentally confirmed on laboratory animals. It was found that photolysis products did not cause skin allergic diseases and had no effect on workers' immunologic reactivity and peripheral blood indices. It was recommended to examine the state of copyists' coagulation system when carrying out preventive medical check-ups. (Author abstract) 2 refs. In Russian.

**085451 INFLUENCE OF INSTRUMENT GEOMETRY AND FILTER CHOICE ON DENSITY AND DOT AREA MEASUREMENT.** This research project was intended to shed light on the factors which account for different color density and dot area readings being produced by various densitometers applied to the same print sample. The experiments showed that interchanging illumination and detection has no effect, but that even small deviations from the 0°/45° position can give a false reading in the case of measurement without polarization. No systematic deviations were observed when the aperture angle or the size of the measurement patch were adjusted. Major discrepancies were found when different filters were used. (Edited author abstract) 4 refs.

## Quality Assurance

**085452 PRINT QUALITY: THE FACTORS INFLUENCING PRINT QUALITY AND WAYS TO MEASURE IT.** A set of objective definitions for print quality is sought. A measurement system that is also developed rates a print sample over a wide range of performance values relating to print quality. The ultimate goal is to rate

printer technologies, as well as commercial printers, on the basis of print quality without relying on subjective, variable human judgements. The readability of dots, lines and arcs, the blank area factor minimization, property of symbols, grid design, dot size, and shape, character shape, position deviations, edges and grey level variance are considered.

**085453 COMMENTS ON: 'THE FUNCTION AND PERFORMANCE OF THE STAINLESS STEEL SCREEN DURING THE SCREEN-PRINT INK TRANSFER PROCESS' (ISHM VOL. 10/2, 1-8, 1987).** The screen printing model proposed in the stated paper by D.E. Riemer appears conceptually sound but is found to be deficient in its analysis. Not all modeling assumptions are stated. Some of the stated assumptions are unwarranted while others require a closer scrutiny. The unstated assumptions are discussed in this paper. It is found that these assumptions restrict the generality of the analysis presented, with the result that misleading calculations are performed. Mistakes detected in the main derivations of the article cast doubt on many of the article's conclusions. Alternate derivations are made, along with suggestions for the general improvement of the model. (Edited author abstract) 23 refs.

## Thermal Effects

**085454 COLOR THERMAL-TRANSFER PRINTING.** The thermal-transfer process is simple in principle, but its implementation for high-quality printing is quite complex. Some of the engineering challenges are described and it is shown how CalComp solved them in designing a series of color printers. By repeating the process three times using combinations of inks of the three primary subtractive colors (yellow, magenta, and cyan), colors can be produced across the full spectrum.

## PRINTING MACHINERY

### Computer Aided Design

**085455 TAMING THE HOT HEADS.** The high temperature of a dot-matrix impact (DMI) print head during operation often reduces throughput because the printer must slow the printing rate at various times during printing to let the head cool off. This inefficiency was reduced through new head design that permits the head to run cool. The plan of action involved considerable mathematical work, CAD, and optimization using prototype models. A summary of the process by which they maximized the efficiency of a DMI print-head design is presented.

**Control** See Also COMPUTER PERIPHERAL EQUIPMENT—Printers.

**085456 DESIGNING A HIGH-SPEED PAGE PRINTER CONTROLLER.** In a desktop page printer, the engine outperforms the controller. The engines are capable of printing at a rate of six or more pages per minute, while the controllers often feed the printer data at less than one page per minute. The controller bottleneck is a serious problem in forms processing, where the printer must turn out many different form sets every day. Placing the printer controller in the computer lets the computer's microprocessor handle memory-intensive page makeup and processing operations. The controller writes the byte stream to the print engine. This approach eliminates

duplicating parts of the computer system, such as chassis, memory, and power supply.

Ellison, Phil (Electronic Form Systems, Carrollton, TX, USA). *Byte* v 12 n 10 Sep 1987 p 225-226.

## Performance

**085457 LESS WASTE WITH ROTOGRAVURE PRINTING MACHINES.** In the printing industry, control technology has to keep pace with continuous mechanical developments. There is no other way of achieving high printing speeds, less waste, faster and easier reel changing during operation and high availability of the system as a whole. Features and capabilities of this machinery are reported. (Author abstract)

Raum, Helmut (Siemens AG, Erlangen, West Ger). *Energy Autom* v 9 n 4 Jul-Aug 1987 p 20-24.

## Thermal Effects

**085458 GRUBOWARSTOWE GLOWICE TERMOPISZACE.** [Thick-Film Thermal Print Heads]. This paper presents the analysis of the employed thermal print heads considering their development methods especially thick-film technology. The main technological problems and methods of that solution are presented. The selection of materials, screens and masking methods are considered. The practical realization of the two-line alpha-numeric thermal print head is considered. (Edited author abstract) In Polish. 11 refs.

Drilling See DRILLS—Carbide.

## Evaluation

**085459 RESOLUTION AS AN EXPOSURE DETERMINANT FOR NEGATIVE-ACTING PRESENSITIZED PRINTING PLATES.** This work was performed to test the practicality of using resolution to determine the proper printing exposure for several US available graphic arts presensitized negative-acting printing plates. Standard techniques employed by UGRA and FOGRA of West Europe for determining the optimum printing exposure of positive-acting presensitized plates were employed. Additional data was gained on the resultant photographic images produced. A comparison of these results versus results obtained using the plate manufacturer's recommendations is also included. Results indicate that this technique is not fully applicable to all the negative-acting presensitized plates available in the US. (Author abstract) 8 refs.

Photolysis See PRINTING—Offset.

## Plastic

**085460 STRESS-STRAIN STATE OF SCREEN PHOTOPOLYMER PLATES.** Photopolymer printing plates are widely used for the production of various forms of publications. A method of numerical investigation of the stress-strain state of the screen elements of Tselfot-2 (type B) illustration photopolymer plates is presented. It was established that the strains in the photopolymer material are less under the action of the drying oil than in air. The proposed method of a numerical experiment makes it possible to investigate the strains of the material of a printing plate taking into consideration the change in its mechanical characteristics under production conditions. 7 refs.

## PRINTING PRESSES See Also LITHOGRAPHY—Materials.

## Computer Applications

**085461 TRENDS IN WEB PRINTING.** The move toward central-impression (CI) cylinders on flexographic web presses, which provide improved speed, clarity, and resolution over stack presses, has been a major trend. The main advantage of a central-impression press is that the web stays on the CI cylinder instead of traveling from one impression cylinder to another, as on a stack press. Also, with its print units directly geared to a single drive gear, a CI press can better provide tight, crisp registration from one color to the next. Microprocessor controllers that permit fast thumbwheel setup of printing stations and push-button precision print positioning have resulted in quicker flexo job changeover and higher speeds for shops with many short runs. Also, more and more video scanners are being used for off-press web viewing and monitoring.

**085463 PROBABILISTIC VERSUS FUZZY REASONING.** This paper shows how to solve problems using probability theory that the fuzzy approaches claim probability cannot solve. By using the view that probabilities are a measure of belief in a proposition in a particular context, limitations imposed by the frequency interpretations of probability are avoided. The various fuzzy approaches (fuzzy sets, fuzzy logic, possibility theory and higher order generalizations) seem to fill the gap caused by the restricted frequency interpretation. Close examination shows that the fuzzy approaches have exactly the same representation as the corresponding probabilistic approach and include similar calculi. The probabilistic approach assumes less information when the calculi differ. (Author abstract) 18 refs.

**085466 NOTE ON MAXIMIZED LIKELIHOOD SETS.** An important tool for decision making is in many cases Bayesian statistical inference. But sometimes the prior information needed for applying this method is only partially known. This note shows that the posterior measure under a partial prior information, which is constructed on the maximized likelihood function, is compatible with the Bayesian properties of the likelihood sets. (Edited author abstract) 7 refs.

**085467 CONFIDENCE COEFFICIENT OF APPROXIMATE TWO-SIDED CONFIDENCE INTERVALS FOR THE BINOMIAL PROBABILITY.** The confidence coefficient of a two-sided confidence interval for the binomial parameter  $p$  is the infimum of the coverage probability of the interval as  $p$  ranges between 0 and 1. The confidence coefficients for five different approximate confidence intervals are computed and compared to the confidence coefficient for the two-sided C.J. Clopper-E.S. Pearson confidence interval. J.W. Pratt's approximation method yields virtually the same confidence coefficients as the Clopper-Pearson interval, and is easily computed without resorting to iterative methods. (Author abstract) 12 refs.

**085468 LOWER BOUND ON MAXIMA OF GAUSSIAN PROCESSES.** This paper presents an alternative lower bound on  $P(\chi_7)$ . The bound is based on the discretization of the time parameter and a theorem that provides a bound on the absolute value of the differences between the largest value distribution of the serial approximation and of a stationary independent series having the same marginal distribution response. It can be optimized relative to the number of samples and one other parameter. 7 refs.

**085469 GENERAL THEORY OF FUZZY PLAUSIBILITY MEASURES.** The purpose of this paper is to present a fuzzification of probability theory, or more precisely to give a fuzzification of plausibility measures first introduced by Shafer in 1976. Although plausibility measures include probability measures as well as possibility measures, it is a typical result of this theory that only a fuzzification of possibility measures is attainable, while a fuzzification of probability measures seems to be impossible. Moreover with regard to fuzzy plausibility measures we specify a concept of mean values and entropies, which can be considered as a direct generalization of the classical notions of mean value and entropy based upon probability measures. (Author abstract) 21 refs.

**085470 FURTHER RESULTS ON DISCRIMINATION WITH AUTOCORRELATED OBSERVATIONS.** This paper considers the estimation of the actual error rates of Fisher's linear discriminant function formed from training data which are serially correlated. The asymptotic bias of the so-called plug-in error rate is given for multivariate training data following a first order autoregressive model. The authors' earlier work on the performance of Fisher's linear discriminant function relative to its version using maximum likelihood estimates obtained under the appropriate correlation model, is reconsidered. A correction is noted to their results on the differences in the individual error rates of these two linear discriminant functions. (Edited author abstract) 14 refs.

**085471 RECURRENT COMPETITIVE BIDDING.** In this review the approaches will be considered under four headings; basic probabilistic approaches, game theoretic approaches, probabilistic strategy approaches and non-price approaches. In the next sections the review concentrates on models that have been applied to the suppliers' problem of selecting a bid price from the cost estimate that they have calculated. This problem is virtually identical to that of a customer who is competing against other customers to purchase some desirable object from a sole supplier who invites bids for the object. The best known example of this is a government auction of drilling rights on tracts of land or sea to oil companies. 35 refs.

**085473 POOLING EXPERT OPINIONS ON PROBABILITY DISTRIBUTIONS.** When several probability distributions are to be synthesized into one, there are certain consistency requirements that generally should be satisfied. They include symmetry, continuity, conservation of form, Bayesian coherence, and application consistency. A vector space formulation of Bayes' theorem is used to derive a convenient restatement of Bayesian coherence. It is shown that a logarithmic pooling formula satisfies the requirements of Bayesian coherence, symmetry, and continuity. It is possible to satisfy the requirements of application consistency in some specific contexts; this is illustrated by an example drawn from highway bridge loads. (Author abstract) Refs.

**085476 NOTE ON THE AVERAGE-CASE BEHAVIOR OF A SIMPLE DIFFERENCING METHOD FOR PARTITIONING.** Given  $n$  positive values we wish to partition them into two subsets such that the difference between the sums of the subsets is minimized. Karp and Karmarkar have shown that a fairly complicated linear-time differencing algorithm achieves, a certain difference for a broad class of probability distributions. Their work left open the question of how two simple and more natural implementations of the algorithm behaved. In this paper, under the assumption that the input values are uniformly distributed, we show that one of these algorithms is not nearly so effective, confirming empirical observations of Karp. (Edited author abstract) 7 refs.

**085478 ESTIMATION OF PROBABILITY TAILS BASED ON GENERALIZED EXTREME VALUE DISTRIBUTIONS.** For high reliability devices or structures it is not uncommon that the probabilities to be estimated are lower than  $10^{-6}$ . In such cases the standard methods of the empirical fit approach and the counting approach may become impractical. In this paper the estimation problem is handled by extrapolation methods which give an approximate expression of an entire probability tail on the basis of the classical and generalized Extreme Value Theory. Comparative performance of these methods, with respect to the classical ones, are drawn by means of a simulation study, which has taken into account the effect of the sample size, the population being investigated and the estimation method. (Author abstract) 11 refs.

**085479 BOOLE-BONFERRONI INEQUALITIES AND LINEAR PROGRAMMING.** We present a method to obtain sharp lower and upper bounds for the probability that at least one out of a number of events in an arbitrary probability space will occur. The input data are some of the binomial moments of the occurrences, such as the sum of the probabilities of the individual events, or the sum of the joint probabilities of all pairs of events. We develop a special, very simple linear programming algorithm to obtain these bounds. The method allows us to compute good bounds in an optimal way, utilizing only the first few terms in the inclusion-exclusion formula. In a numerical example we approximate the

probability that a Gaussian process runs below a given level in a number of consecutive epochs. (Edited author abstract) 25 refs.

**085481 NOTE ON MULTIVARIATE DISTRIBUTIONS WITH SPECIFIED MARGINALS.** Johnson and Tenebein describe a procedure for generating random values from a bivariate distribution with specified marginal forms an any required correlation between the two variables. This note shows that the approach can be extended to produce values from general multivariate distributions in a straightforward manner. This work, provides a fast and simple procedure for generating an n dimensional distribution, with any required marginals and specified correlations, which can be used in simulation models. 3 refs.

Butterworth, Nicholas J. (Bank of England, London, Engl). *J Oper Res Soc* v 39 n 5 May 1988 p 477-479.

**085482 RESAMPLING-TYPE ERROR RATE ESTIMATION FOR LINEAR DISCRIMINANT FUNCTIONS. PEARSON VII DISTRIBUTIONS.** This paper extends the work of a previous paper on error rate estimation for linear discriminant functions by considering additional non-Gaussian distributions from the Pearson VII family. The Pearson VII family is an elliptically contoured family of probability densities with a parameter  $m$  that controls the tail length of the distribution. For  $m > 2$  (i.e. reasonably light tails) the estimators perform similarly to previous Gaussian case studies and previous simulated exponential and uniform distributions. For  $m \leq 1.6$  (i.e. heavy tails) results similar to previous Cauchy cases are obtained. The 0.632 estimator generally performed best for large  $m$ , but it does not perform as well as the  $e_0$  and convex bootstrap when the tails are heavy. The positive bias of  $e_0$  no longer pertains when the tails are heavy. (Author abstract). 10 refs.

**085484 COMMENT ON 'AN ALGORITHM FOR EXACT FAULT-TREE PROBABILITIES WITHOUT CUT SETS' BY L. B. PAGE, ET AL.** A direct evaluation algorithm was presented by L. B. Page and J. E. Perry (1986) that is based on a bottom-up modularization of the fault tree and a top-down recursive probability calculation. The point is made here that direct evaluation techniques that do not use cut sets have not been taken seriously in the past and that one reason for this is that recursion is not permitted in Fortran, which is the language used by most engineers. Several additional computer codes that evaluate a fault tree directly are described. One of the codes is written in PL/1, and uses techniques of pat-

tern-recognition and list-processing to evaluate fault-tree probabilities. Two other codes illustrate the use of Lisp and Prolog to implement recursive algorithms for the direct evaluation of fault trees. 7 refs.

## Analysis

**085485 PWM SOLUTIONS TO NORMAL, LOG-NORMAL AND PEARSON-III DISTRIBUTIONS.** It has been considered that a new statistical parameter estimation method using probability weighted moments (PWM) is difficult to be applied for the distributions that cannot be expressed in an inverse form. The authors show in this paper that it has been successfully applied and that the analytical PWM solutions were obtained for the representative distributions of non-inverse type, that is, Normal, 3-parameter Lognormal and 3-parameter Pearson-III distributions. The PWM estimate of the standard deviation of the Normal distribution turned out to be unbiased and having a form of a linear combination of samples (Author abstract) In Japanese. 17 refs.

## Estimation

**085489 ON RELATIVE ACCURACY OF PWM ESTIMATES OF NORMAL AND 3-PARAMETER LOGNORMAL DISTRIBUTIONS.** Following the successful derivation of PWM solutions for Normal and 3-parameter Lognormal distributions by the authors, this paper presents their relative accuracy in comparison with other parameter estimation procedures such as Moment, Maximum-likelihood, Quantile and Sextile methods

through Monte Carlo simulation experiments. Simulation results revealed that PWM estimates of quantiles are unbiased for Normal distribution and less biased than those of Moment method for Lognormal distribution with a large coefficient of skewness. It was also revealed that rmse of PWM estimates of quantiles is as small as that of Moment method for Normal distribution but larger for Lognormal distribution. (Author abstract) In Japanese. 13 refs.

**085490 MONOTONE STOPPING GAMES.** We consider the extension of optimal stopping problems to non-zero-sum strategic settings called stopping games. By imposing a monotone structure on the pay-offs of the game we establish the existence of a Nash equilibrium in non-randomized stopping times. As a corollary, we identify a class of games for which there are Nash equilibria in myopic stopping times. These games satisfy the strategic equivalent of the classical 'monotone case' assumptions of the optimal stopping problem. The results are relevant to economics and management science. (Edited author abstract) 11 refs.

**085491 PARALLEL SEARCHES OF GAME TREES.** A two-person perfect-information game is represented by a minimax game tree and, by solving the tree, we can obtain the result of the game when both players choose perfect moves at all the positions. To this end, various search procedures have been proposed. In this paper, these procedures are modified to implement them on a parallel computer consisting of  $m$  processors, and variations of the computation time are investigated with  $m$  being a parameter. As a theoretical result, we point out that the speedup ratio of the computation time of solving a game tree by  $m$  processors to that by 1 processor may become larger than  $m$  (acceleration anomaly) or smaller than 1 (detrimental anomaly) in general. (Edited author abstract) 17 refs.

**085492 POSITIONAL PURSUIT PROBLEM IN MANY-PURSUER DIFFERENTIAL GAME.** The article solves a differential game of team pursuit. It was previously assumed that all pursuers know the evader control function at every time during the entire period of the game up to a given time, i.e., the pursuers are informed about the previous history of the evader control. However, such a formalization of the conflict process is not always realistic, because to know an opponent's control is to understand his choices, and only very rarely is that ever possible, as, eg., when a tracker is used. It is more realistic to assume knowledge of the phase state of the game, and so the objective of the present article is to develop a certain modification of the above-described method for the solution of many-pursuer differential games to allow the pursuers to formulate their control on the basis of the position (status) of the game at the given time. This is

accomplished by the introduction of a certain fictitious scout system, whose motion is utilized by the pursuers at certain fixed times to correct their own paths. 9 refs.

**085493 ANALYTIC METHOD FOR THE SOLUTION OF THE APPROACH-DEVIATION PROBLEM IN A LINEAR DIFFERENTIAL GAME WITH TERMINAL PAYOFF FUNCTION.** We consider some questions regarding the solving of approach-deviation problems in linear differential games with terminal payoff function, which depends on the end of the trajectory and estimates the outcome of the game. The construction of the strategies of the players has in general a nonconstructive character and, therefore, the problem of the creation of methods, allowing to construct in a simple manner the controls of the players for definite classes of games, is important. In this paper, making use of the concept of an H-convex set, we succeed to describe a sufficiently large class of games in which the players may use the so-called stroboscopic strategies. (Edited author abstract)

**085495 MAPS, GAMES AND THINGS IN-BETWEEN: MODELLING ACCOUNTS OF CONFLICT.** This paper describes a way of combining hypergame problem-structuring with the use of cognitive maps to elicit and use information about perceptions in conflicts. In bringing these two forms of analysis together, a new form of model is introduced, based on the notion of a 'decision arena'. The approach is illustrated by reference to a project carried out in a local government setting, and some general conclusions drawn as to its potential advantages. (Author abstract) 24 refs.

Bennett, P.G. (Univ of Sussex, Brighton, Engl); Cropper, S.A. *Eur J Oper Res* v 32 n 1 Oct 1987 p 33-46.

**085496 PURSUIT-EVASION DIFFERENTIAL GAMES WITH UNCERTAINTIES IN DYNAMICS.** Pursuit-evasion differential games with bounded uncertainties in dynamics are considered. As one may expect, the classical concepts of optimality, of the value of a game and of the saddle point do not apply to such games. The 'value' become dependent on the (unknown) uncertainties and is located somewhere between certain bounds which can be determined as solutions (if they exist) of a pair of antisymmetric Isaacs equations. A new method employing V-functions is then proposed for determining the strategies assuring the capture for any realization of uncertainties. The ideas are illustrated by examples. (Author abstract) 28 refs.

**085497 BARRIER IN A PURSUIT-EVASION GAME WITH TWO TARGETS.** We consider the problem of determining the barrier in a pursuit-evasion game involving two objectives in which the evader seeks to reach his own safety zone before capture by the pursuer, and the pursuer seeks capture while avoiding the evader's safety zone. The boundaries of the two winning regions are determined and are shown to be semi-barriers for the players using the Liapunov method. The intersection of the semi-barriers is shown to be non-empty and is the

barrier for the problem. The concept of Isaac's barrier is thus extended to the game which involves two targets associated with two objectives for each player. (Edited author abstract) 5 refs.

Skowronski, J.M. (Univ of Queensland, St. Lucia, Aust); Stonier, R.J. *Comput Math Appl* v 13 n 1-3 1987 p 37-45.

**085498 GEOMETRIC APPROACH TO THE CONSTRUCTION OF THE BARRIER SURFACE IN DIFFERENTIAL GAMES.** In the present work we examine Isaacs' geometric method for the construction of the barrier surface in differential games. We are thus led, in a natural way, to a new (geometric) second-order necessary condition that a valid barrier surface must satisfy. This helps us, on the one hand, to clarify the appearance of a previously discovered qualitatively new type of barrier surface when the problem parameters enter a certain region of the parameter space, and, on the other hand, our systematic analysis also helps us to identify new interesting regions in parameter space where the barrier surface qualitatively differs from previously observed patterns. (Author abstract) 9 refs.

Pachter, M. (CSIR, Pretoria, S Afr); Miloh, T. *Comput Math Appl* v 13 n 1-3 1987 p 47-67.

**085499 SIMPLE-MOTION PURSUIT-EVASION IN THE HALF PLANE.** We consider a pursuit-evasion differential game in the half plane in which the players, i.e. the pursuer and the evader, have simple motion and thus are 'pedestrians' a la Isaacs. In the present paper we present a complete analysis of this state-constrained pursuit-evasion differential game for the case where the pursuer is faster than the evader. (Author abstract) 3 refs.

Pachter, M. (CSIR, Pretoria, S Afr). *Comput Math Appl* v 13 n 1-3 1987 p 69-82.

**085500 SIMPLE LINEAR PURSUIT-EVASION GAMES.** We approach the qualitative games of pursuit-evasion using differential game with terminal cost. The terminal time is then used as a parameter to test capture and avoidance. Evasion problems previously introduced without complete solutions, are shown to satisfy the present conditions for evasion. (Author abstract) 5 refs.

**085501 APPROACH TO THREE-DIMENSIONAL AIRCRAFT PURSUIT-EVASION.** An algorithm for obtaining a state-feedback control law for near-optimal aircraft pursuit-evasion in three dimensions is outlined. Key features of the approach are the use of singular-perturbation ideas to decouple the dynamics of each of the two players and the use of a reference frame that decouples the slow subsystem extremals of one player from those of the other. The resulting subproblems are then tractable for closed-loop solution, and the solutions may be combined to give a control law feasible for real-time implementation. Compared with past analyses of pursuit-evasion games, our dynamic model is higher order and more realistic; therefore, our results should be of practical value for aircraft control. And because we use fewer time-scales than were used in past analyses of flight dynamic problems by singular-perturbation methods, our algorithm should be more accurate. (Author abstract) 37 refs.

**085502 AIRCRAFT PURSUIT-EVASION PROBLEMS WITH VARIABLE SPEEDS.** Aircraft pursuit-evasion encounters in a plane with variable speeds are analyzed as a differential game. An engagement-dependent coordinate system confers open-loop optimality on the game. Each aircraft's optimal motion can be represented by extremal trajectory maps which are independent of role, adversary and capture radius. These maps are used in two different ways to construct the feedback solution. Some examples are given to illustrate these features. The paper draws on earlier results and surveys several existing

papers on the subject. (Author abstract) 28 refs.

Prasad, U.R. (Indian Inst of Science, Bangalore, India); Rajan, N. *Comput Math Appl* v 13 n 1-3 1987 p 111-121.

**085503 TWO-TARGET GAME ANALYSIS IN LINE-OF-SIGHT COORDINATES.** The engagement between two aggressively operating similar aircraft armed with boresight limited 'all-aspect' missiles is modeled as a two target differential game between 'two identical cars'. By using a line-of-sight coordinate system the symmetry of the problem can be exploited leading to a reduced complexity in the game of kind analysis. The barrier trajectories are obtained in a closed form allowing us to generate closed barrier surfaces with a reasonable computational effort. These barrier surfaces enclose the 'winning zone' of each player and the 'region of mutual kill'. The analysis reveals several new features not encountered in previous studies. (Author abstract) 16 refs.

**085504 STOCHASTIC TWO-TARGET PURSUIT-EVASION DIFFERENTIAL GAME WITH THREE PLAYERS MOVING IN A PLANE.** A stochastic version of a two-target homicidal chauffeur pursuit-evasion differential game between a player P on one side and players  $Q_1$  and  $Q_2$  on the other side is considered. This is used to model a dogfight between two very agile players,  $Q_1$  and  $Q_2$ , and a much less maneuverable player P. Sufficient conditions on optimal strategies are derived. These conditions require the existence of a properly smooth solution to a nonlinear partial differential equation on a generalized torus in  $R^4$ . By applying a finite-difference method, the equation is solved numerically, and optimal strategies are computed. (Author abstract) 22 refs.

Yavin, Y. (CSIR, Pretoria, S Afr). *Comput Math Appl* v 13 n 1-3 1987 p 141-149.

**085505 STOCHASTIC GUIDANCE LAWS IN SATELLITE PURSUIT-EVASION.** The presence of noise in the driving equations and in the data makes the stochastic version of two-player pursuit-evasion differential games difficult to define unequivocally, even for very low-order dynamic models. The analysis of specific problems of this type often do not include trajectories as determined by using the guidance algorithms in the equations of motion. More often, the problems are studied analytically to determine certain functions which are necessary or relevant to a solution. In the present study, a guidance algorithm is described and derived before being applied to a specific two-spacecraft encounter. Numerical results are presented graphically for a specific set of independent parameters and input variables. 2 refs.

Merz, A.W. (Lockheed Palo Alto Research Cent, Palo Alto, CA). *Comput Math Appl* v 13 n 1-3 1987 p 151-156.

**085506 ON CLOSED-LOOP CONTROLS IN PURSUIT-EVASION.** A hybrid algorithm is introduced in order to generate optimal closed-loop controls in a pursuit-evasion problem. The algorithm is composed of a differential dynamic programming method and a singular perturbation technique. The first mentioned method is used in those parts where the latter is weak. The method so created has an open-loop character. By having the open-loop solution updated as often as possible when new measures of the states have been estimated, the method will be near-optimal closed-loop. The game problem is discussed in terms of optimistic or pessimistic strategies, based on assumptions of the evader's strategy. In practice, the evader he may not do his best. The demonstrative example is in the horizontal plane, formulated as a game of degree. The pursuer uses a variable speed model with throttle and turn controls. The computer requirements

can be kept to a reasonable level, and the new algorithm can be implemented on an airborne computer. (Author abstract) 23 refs.

Jaemark, B. (SAAB-SCANIA AB, Linköping, Swed). *Comput Math Appl* v 13 n 1-3 1987 p 157-166.

**085507 PURSUIT-EVASION IN MEDIUM-RANGE AIR-COMBAT SCENARIOS.** A procedure for developing strategies for unmanned combat is presented that consists of modeling the air combat scenario as a differential game problem - or a series of such problems and applying differential game theory. Full order modeling of 1 vs 1 engagements with medium range missiles is discussed, including constraints in dynamic pressure, radar visibility and load factors. As an example the open-loop solution of a characteristic pursuit-evasion problem is presented and compared to a simulation result using a typical air combat simulation computer program. (Edited author abstract) 8 refs.

**085508 PARTIALLY OBSERVABLE LINEAR-QUADRATIC STOCHASTIC PURSUIT-EVASION GAMES.** A linear-quadratic differential game in which the system is affected by additive as well as multiplicative disturbances and both players have access to the same noisy measurements is solved. Using the concept of projection estimates, the problem is reduced to a completely observable one and the optimal linear nonanticipative strategy is found via a deterministic Hamilton-Jacobi-Bellman-Isaacs theory. (Author abstract) 8 refs.

Chan, W.L. (Chinese Univ of Hong Kong, Hong Kong); Ng, S.K. *Comput Math Appl* v 13 n 1-3 1987 p 181-189.

**085509 PURSUIT-EVASION DIFFERENTIAL GAMES WITH DECEPTION OR INTERRUPTED OBSERVATION.** Three stochastic pursuit-evasion differential games involving two players, E (the evader) and P (the pursuer), moving in the plane are considered. In the first game, the case where E induces errors in P's measurements of the bearing  $\beta$  of E from P and controls the size and direction of these errors, is considered. In the second game, the case where P receives readings of two false targets, which are seen within the same range of P, but with different bearing angles, is considered. In the third game, the case where P observes the range  $r$  of E from P, but has interrupted observation of  $\beta$ , is considered. Results are derived for all three cases. A procedure is suggested for computing weak suboptimal pursuit strategies, and these are computed for a variety of cases. (Edited author abstract) 13 refs.

**085511 n-PERSON NONCOOPERATIVE DISCOUNTED VECTOR VALUED DYNAMIC GAME WITH A STOPPED SET.** The optimization problem of an n-person noncooperative discounted vector valued dynamic game with a stopped set is investigated. A D-convex equilibrium point as the optimization criterion in the game is defined under a domination structure of a convex cone D. We show that there exists such a D-convex equilibrium point in the game system. A modified game system of the original game is formulated which is weighted by a vector factor so that an equilibrium point of the modified game system is still a D-convex equilibrium point of the original game system. Conversely, under some additional conditions a D-convex equilibrium point

will become an equilibrium point of the modified game system. Further, a relation of D-convex equilibrium point and the super-gradient is discussed. (Author abstract) 13 refs.

Lai, H.-C. (Nat'l Tsing Hua Univ, Taiwan); Tanaka, K. *Comput Math Appl* v 13 n 1-3 1987 p 227-237.

**085512 ON WORST CASE DESIGN STRATEGIES.** For sequential decision processes, we consider the problem of obtaining the min-max strategy which minimizes the worst case performance. This is a game against nature, where the controller attempts to minimize a specified cost criterion, while nature attempts to maximize it. It is apparently a folk theorem that such a min-max strategy can be obtained by means of a dynamic programming like recursion, even though we have not seen any general proof of this, applicable to stochastic systems, which does not rely on the existence of a saddle point. We prove this theorem, and also examine the precise roles of the strategy sets allowed to the minimizer and the maximizer in determining the upper value of the game. Improvements in the results for the case of deterministic systems, and generalizations to continuous time systems are indicated. (Author abstract) 4 refs.

**085516 SIMPLE GAME, VOTING REPRESENTATION AND ORDINAL POWER EQUIVALENCE.** The paper gives an analysis to the question of whether the Shapley-Shubik (SS) and Banzhaf-Coleman (BC) power indices have the same ordering of power values for members in a simple game. To this ordinal power equivalence problem, the following results are obtained: The two power indices are always ordinally equivalent in weighted majority games, which are defined as simple games with a voting representation. They are not always ordinally equivalent in six- or more-member simple games which have no voting representation. Through the analysis, we get the noticeable difference between the two power indices. It is that the ordering of the BC power values for members in a simple game is always the same as it in its veto-holder extension game, but the ordering of the SS power values is not always the same. **085520 NOTE ON CLEMHOUT AND WAN'S DYNAMIC GAMES OF COMMON PROPERTY RESOURCES.** Recently, S. Clemhout and H.Y. Wan provided solutions to a class of Stochastic differential game models concerning common property resources. However, they only established closed-loop strategies for the infinite-horizon problem using the Kushner test. In this paper, we provide closed-loop feedback solutions to their game in a finite-time horizon with deterministic evolution dynamics. (Author abstract) 6 refs.

Plourde, C. (York Univ, Ont, Can); Yeung, D. *J Optim Theory Appl* v 55 n 2 Nov 1987 p 327-331.

**085521 COMPARISON OF THE SOLUTIONS OF LINEAR AND NON-LINEAR POSITIONAL DIFFERENTIAL GAMES OF ENCOUNTER.** A positional differential game of encounter of a non-linear, conflict-controlled system with a given target set is considered. Sufficient conditions for a successful encounter of the initial system with the target set are given. The differential game problem of encounter between two objects with restricted manoeuvrability is solved. The equations of motion of the objects and the constraints imposed on the controls are given using the same relations as those in the differential game known as the two-car game. It is assumed that both objects have restricted manoeuvrability and the game takes place over a fixed time interval. A positional strategy is constructed for the pursuer guaran-

teering that it arrives at a previously specified distance from the pursued at the instant of game termination. (Edited author abstract) 15 refs.

Pashkov, A.G. *Appl Math Mech* v 50 n 4 1986 p 421-428.

**085522 ON AN ALTERNATIVE FOR PURSUIT-EVASION GAMES IN AN INFINITE TIME INTERVAL.** The structure of phase of differential pursuit-evasion games is studied for the case when the evader is subjected to information discrimination with an advance by  $\delta > 0$ ,  $\delta = \text{const}$ . The method of transfinite iteration of the pshechichnyi operator is used to establish an alternative for differential pursuit-evasion games in an infinite time interval. (Author abstract) 12 refs.

Azamov, A.A. *Appl Math Mech* v 50 n 4 1986 p 428-432.

**085523 ON DISCRETE LOWER  $\Pi$ -STRATEGIES.** Two-person zero-sum differential games of survival are investigated. It is assumed that player I, as well as player  $\Pi$ , can employ during the course of the game any lower  $\Pi$ -strategy,  $\Pi(t_i)$  being a finite partition of  $[t_0, \infty)$ . The concept of a discrete lower  $\Pi$ -strategy is introduced and it is shown that if player I ( $\Pi$ ) confines himself to the space of discrete lower  $\Pi$ -strategies, being a subset of the space of lower  $\Pi$ -strategies, then he will be able to force the same lower (upper) value as if he could employ any lower  $\Pi$ -strategy. Since we do not use any deep facts about differential games, the results contained here might be extended to continuous games. (Author abstract) 8 refs.

**085527 GAME-THEORETIC VERSION OF THE MAXIMUM PRINCIPLE WITH DISCRETE PARTIALLY ORDERED TIME.** In addition to traditional game-theoretic problems related to developing optimality principles, establishing their realizability and finding solutions, it is of considerable interest to discover relationships between the separate optimal functioning of components (units) of a system and the functioning of their system as a whole. We refer to assertions which reduce the

optimality of operation of a system as a whole to the optimal operation of its units (components) as a game-theoretic version of the maximum principle. It is this problem which is the subject of the paper. Adopting the traditional terminology of games theory, we refer to individual representatives of interests or points of view, or sometimes the interests or points of view themselves, as players. 6 refs.

**085528 VERY SIMPLE DIFFERENTIAL GAME WITH CHOICE OF THE TIME IN MIXED STRATEGIES.** A program differential game on a straight line is considered in which the pursuer P minimizes and the evader E maximizes the probability of evading the r rendezvous at the instant at which the game is stopped. The pursuer controls the duration of the game, whereas the evader controls the speed variation. The optimal mixed strategies of the players are determined, as well as the payoff of the game. (Author abstract) 9 refs.

**085529 THEORIES OF PURSUIT AND EVASION.** We give three elementary definitions of a game of pursuit and evasion in a large class of metric spaces. Our definitions are independent of the theory of differential games. We prove that the three definitions yield the same value of the game, and we study this value as a function of the initial positions of the players and their velocities. Several open problems are stated. (Author abstract) 15 refs.

**085530 NONLINEAR DIFFERENTIAL ENCOUNTER-EVASION GAMES WITH DELAY.** The author investigates the problem of avoiding encounter from a specified initial point (encounter-evasion problem) as described by a differential equation with delay in the state vector and its derivative. He departs from previous treatments in the assignment of different conditions for the possibility of evasion. We find a guaranteed lower bound for the distance from the phase point to the endset. 8 refs.

Konovalov, A.P. *Cybernetics* v 23 n 3 May-Jun 1987 p 418-425.

**085531 INTERPOLATION OF STRATEGIES OF DIFFERENTIAL GAMES UNDER UNCERTAINTY.** The following types of differential pursuit-evasion games are considered: A differential game with inequality constraints on the controls of the players, and differential games with integral payoffs in the case of a fixed or a non-fixed time of termination of the game. A pursuer strategy is constructed that takes into account the incompleteness of information about the control possibilities of the opponent and possible changes in the nature of the game (i.e., going over from antagonistic games to cooperative or stochastic games). These techniques can be extended to a special method of investigation of more complex systems, i.e., multidimensional and nonlinear systems. (Edited author abstract) 8 refs.

Fomenko, A.V. *Autom Remote Control* v 48 n 9 pt 1 Sep 1987 p 1157-1161.

**085532 CLOSED-LOOP STRATEGIES IN CONTINUOUS DYNAMIC GAME WITH MULTI-LEVEL OF HIERARCHY.** The derivation is given of the closed-loop Stackelberg strategy for a class of continuous three-player non-zero-sum differential games using the idea of the team-optimal Stackelberg strategy. The game systems are described by linear state dynamics and quadratic objective functions. A definition of the three-player hierarchical equilibrium is given; then a general theorem which was developed by Basar (1981) is examined and applied to the game under consideration to deduce some sufficient conditions for the solution of the game to exist. A simple example is given. (Edited author abstract) 4 refs.

Jiong, Jiang (Zhejiang Univ, Hangzhou, China). *Int J Control* v 47 n 3 Mar 1988 p 905-913.

**085533 STOCHASTIC TWO-TARGET PURSUIT-EVASION DIFFERENTIAL GAMES IN THREE DIMENSIONS.** Stochastic versions of a three-dimensional two-target 'game of two cars' and a three-dimensional two-target 'homicidal chauffeur' game are considered. These are used to model a dogfight, in the  $(x, y, z)$  space, between a very agile player Q and a less maneuverable player P. A numerical study is conducted, by numerically solving a non-linear partial differential equation, to investigate the role of the parameters of maneuverability, speed and the performance of the 'weapon systems' in the encounter. (Author abstract) 11 refs.

**085534 PURSUIT OF A GROUP OF EVADERS BY A SINGLE CONTROLLED OBJECT.** A quasidifferential pursuit-and-evasion game is considered in which a single controlled object pursues several evaders. Sufficient conditions for the termination of pursuit are established in the class of stroboscopic strategies with memory (SSM). The case of simple motion of the pursuer and the evaders is studied in more detail. In this case, the SSM coincides with parallel pursuit strategy. 13 refs.

**085535 LINEAR DIFFERENTIAL EVASION GAMES WITH LAG AND INTEGRAL CONSTRAINTS.** Starting from previous investigation of linear differential evasion games with integral constraints, the author considers linear differential evasion games from a given initial point (the deviation problem) with lag in the state and velocity vectors under the same constraints. He gives sufficient conditions for the possibility of a deviation from a fixed initial point of the phase space and indicates a method for the computation of the evasion control, as well as a lower estimate from a phase point to the terminal set. 6 refs.

Konovalov, A.P. *Cybernetics* v 23 n 4 Jul-Aug 1987 p 485-491.

**085536 TYPE OF LINEAR GAME WITH MIXED CONSTRAINTS ON THE CONTROLS.** A differential game in which the first person's control is subject to a geometric and an integral constraint. The second person can choose a control, subject to the geometric constraint. The game ends at a given instant. The sets of controls values and the terminal set are of the same type. The conditions are found for the game to the end from a given initial position. The player's controls are constructed, and an example is given. (Edited author abstract) 8 refs.

Ukhobotov, V.I. *Appl Math Mech* v 51 n 2 1987 p 139-144.

**085537 SECOND PLAYER'S STRATEGY IN A LINEAR DIFFERENTIAL GAME.** A linear antagonistic two-person differential game with fixed instant of termination and convex pay-off function is considered. A numerical method is described for constructing the second (maximizing) player's strategy, which guarantees a close-to-optimal result. A computer-checked example is given. (Edited author abstract) 12 refs.

Zarkh, M.A.; Patsko, V.S. *Appl Math Mech* v 51 n 2 1987 p 150-155.

**085538 PROBLEM OF THE NASH EQUILIBRIUM SITUATION IN A POSITIONAL N-PERSON GAME WITH A MEMORY.** The approach of a pencil of trajectories to the terminal set, when the control side uses positional strategies with a memory and is ignorant of the discrete parameter on which both the dynamic system and the terminal set depend, is considered. The set of initial positions for which the problem is solvable is

constructed. It is shown that this set can be constructed by solving several standard problems on approach in positional strategies without a memory and without undetermined parameters. It is also shown that the set has in a certain sense the bridge property which is typical for the solution of positional approach problems with undetermined parameters. (Edited author abstract) 3 refs.

Chistyakov, Yu.E. *Appl Math Mech* v 51 n 2 1987 p 156-161.

**085539 NASH, PARETO, AND STACKELBERG SOLUTIONS IN NON-ANTAGONISTIC TWO-PERSON GAMES.** Nonantagonistic differential games are formalized on the basis of the formal theory of positional antagonistic differential games. All three types of solution are considered in a unified approach. Our concept of a Pareto solution differs from the usual one in allowing for the individual scope of each player. A single structure of strategies for all types of solutions of different types are established. It is shown that the set of solutions of each type is characterized by the solutions of appropriate non-standard (optimal) control problems. The results are illustrated by the example of the plane motion of a material particle subject to the total action of control forces generated by the different players. (Edited author abstract) 10 refs.

Kleimenov, A.F. *Appl Math Mech* v 51 n 2 1987 p 162-166.

**085540 ON A COMPUTATIONAL ALGORITHM FOR SOLVING GAME CONTROL PROBLEMS.** Positional differential game of approach to a target is considered. The construction of the set of positional adsorption (SPA) is studied. Relations are given, on the basis of which an algorithm of approximate computation of the SPA for controlled systems in the plane is developed. (Author abstract) 11 refs.

**085541 STRUCTURAL CHOICES OF 2 VERSUS 1 PURSUIT-EVASION DIFFERENTIAL GAMES.** Problems particular to N versus 1 differential games are investigated based on a 2 versus 1 game. A differential game arises between two sonar (or radar) systems and a target. The target uses a mixed strategy by adding white noise into its controller to hamper the tracking of the sonars. The two structures studied, a centralized and a decentralized structure that correspond to a 1 versus 1 or a 2 versus 1 game formulation, are shown to yield different results. Nash-optimality of each structure is shown to depend on the dynamics of the evader. The study provides insight into the solution of difficult problems specific to N versus 1 games. To illustrate further N versus 1 game problems, a nonoptimal scalar case is presented in which the decentralized structure is proven superior. (Edited author abstract) 10 refs.

**085542 STOCHASTIC TWO-TARGET PURSUIT-EVASION DIFFERENTIAL GAMES IN THE PLANE.** A stochastic version of a two-target homicidal chauffeur, pursuit-evasion differential game (using polar coordinates) is considered. This is used to model a dogfight between a very agile player Q and a less maneuverable player P. First, the case where both players have complete observation of the state of the game is considered. A numerical study is conducted, by solving numerically a nonlinear partial differential equation on a torus in  $R^2$ , to investigate the role of the parameters of speed, maneuverability, and performance of the weapon systems, in the encounter. Second, the model is extended to include the case where player P is jamming player Q's measurements of  $\beta$ , where  $\beta$  denotes the bearing of Q from P. A numerical study is conducted, by solving numerically a nonlinear partial differential equation on a generalized torus in  $R^2$ , to investigate the role of the jamming parameter on the outcome of the combat. (Author

**085543 STOCHASTIC PURSUIT-EVASION DIFFERENTIAL GAMES IN 3D.** A stochastic version of Isaacs's homicidal chauffeur game in the  $(x, y, z)$ -space is considered. This is used to solve a pursuit-evasion problem in the  $(x, y, z)$ -space in which the pursuer has incomplete information on the evader motion. Optimal feedback strategies for the game, and optimal feedback guidance laws for the pursuer, which uses only the measurements available to the pursuer, are computed. A simple suboptimal guidance law for the pursuer is suggested. (Author abstract) 10 refs.

**085544 RECURSIVE SOLUTION OF LINEAR-QUADRATIC NASH GAMES FOR WEAKLY INTERCONNECTED SYSTEMS.** A recursive method is developed for the solution of coupled algebraic Riccati equations and corresponding linear Nash strategies of weakly interconnected systems. It is shown that the given algorithm converges to the exact solution with the rate of convergence of  $O(\epsilon^2)$ , where  $\epsilon$  is a small coupling parameter. In addition, only low-order systems are involved in algebraic computations; the amount of computations required does not grow per iteration and no analyticity assumption is imposed on the system coefficients. (Author abstract) 19 refs.

**085545 PERFORMANCE VERSUS INFORMATIVENESS IN LINEAR-QUADRATIC GAUSSIAN NONCOOPERATIVE GAMES.** We study the impact of informativeness on the performance of linear quadratic Gaussian Nash and Stackelberg games. We first show that, in two-person static Nash games, if one of the players acquires more information, then this extra information is beneficial to him, provided that it is orthogonal to both players' information. A special case is that when one of the players is informationally stronger than the other, then any new information is beneficial to him. We then show that a similar result holds for dynamic Nash games. In the dynamic games, the players use strategies that are linear functions of the current estimates of the state, generated by two Kalman filters. The same properties are proved to hold in static and feedback Stackelberg games as well. (Author abstract) 20 refs.

**085546 DETERMINATION OF PREFERENCES ON THE BASIS OF POST-GAME ANALYSIS OF EVENTS.** A new approach to the investigation of conflicts is proposed. A conflicting interaction of participants shows up in the form of a sequence of events. The game-theoretic interpretation is assigned to the event sequence; that is, the different events are regarded as moves in a game. With such a representation of a conflict, there arises the problem of reconstruction of systems of preferences of the participants on the basis of analysis of the event sequence as a problem of analysis of the structure of the conflict. A method based on modeling the rational behavior of the participants in a game with nonzero sum is proposed for solving the problem. Since a unique solution of the problem cannot be guaranteed, one uses Bayes' formula in making a comparative estimate of the likelihood of different hypotheses. (Author abstract). 10 Refs.

**085548 SADDLE POINT CONDITIONS FOR A CLASS OF STOCHASTIC DYNAMICAL GAMES WITH IMPERFECT INFORMATION.** Nonlinear dynamical games are considered in which one player has full (causal) information on the state and the opponent's measurements and control, while the other one only has partial, possibly noise-corrupted, state information. A dynamic-programming-like algorithm in an extended space is given that, when successful, yields, a saddle point, usually in mixed strategies. This result is used to provide an equilibrium in safe strategies for the case in which both players are restricted to imperfect state information. 12 refs.

**085549 SOCIAL IMPLICATIONS OF NON-ZERO-SUM GAMES.** It is argued that a reorientation of the theory and application of non-zero-sum (NZS) games is needed in order for that discipline to have a beneficial impact on societal problems such as war. Accordingly, a general strategy of cooperation with minimum sanctions (CMS) is developed and applied to prisoner's dilemma (PD) and dollar auction games. It is shown that tit-for-tat-like strategies are appropriate for all PD games, not just iterated PD, and that, contrary to previous consensus, it is rational to cooperate in the single-shot PD. In evaluating NZS strategies in human or computerized tournaments, special NZS scoring rules should be used. A water-division bargaining example is included to illustrate the superiority of the maximum-welfare approach to the Nash bargaining solution. 12 refs.

**085550 SOME REMARKS ON THE HAZARD FUNCTIONS OF THE INVERTED DISTRIBUTIONS.** The probability models of reciprocals of normal, Gamma and Weibull variates are called inverted normal, inverted Gamma and inverted Weibull distributions, respectively. These distributions arise naturally in the study of certain stochastic processes causing wearout failures of mechanical systems. Characteristic features of the hazard functions based on this inverted class of distributions are discussed and their possible uses are explored. Hazard functions and mean residual life of inverted normal, inverted Gamma and inverted Weibull are compared with the normal, Gamma and Weibull hazards. (Edited author abstract) 9 refs.

## Optimization

**085551 IMPROVING ON BOLD PLAY AT CRAPS.** We derive heuristically a strategy we believe to be nearly optimal at craps (in the sense of maximizing the probability of reaching a specified goal). We then prove rigorously (with the aid of a computer) that this strategy is superior to bold play on 'don't pass,' regardless of the ratio of one's initial fortune to one's goal. It is emphasized that the analysis assumes infinitely divisible capital and no betting limits. Of course, a gambler cannot bet what he does not have. (Edited author abstract)

**085552 UPPER BOUND ON THE PERFORMANCE OF QUEUES WITH RETURNING CUSTOMERS.** Multiple channel queues with Poisson arrivals, exponential service distributions, and finite capacity are studied. A customer who finds the system at capacity either leaves the system forever or may return to try again after an exponentially distributed time. Steady state probabilities are approximated by assuming that the returning customers see time averages. The approximation is shown to result in an upper bound on system performance. (Author abstract) 9 refs.

**085555 ON SOJOURN TIME IN JACKSON NETWORKS OF QUEUES.** This paper is about representations for equilibrium sojourn time distributions in Jackson networks of queues. For a network with  $N$  single-server nodes let  $b_i$  be the Laplace transform of the residual system sojourn time for a customer 'arriving' to node  $i$ , 'arrival' meaning external input or internal transfer. The transforms  $\{b_i; i=1, \dots, N\}$  are shown to satisfy a system of equations we call the network flow equations. These equations lead to a general recursive representation for the higher moments of the sojourn time variables  $\{T_i; i=1, \dots, N\}$ . This recursion is discussed and then, by way of illustration, applied to the single-server Markovian queue with feedback. (Author abstract) 14 refs.

Lemoine, Austin J. (Ford Aerospace & Communication Corp, Palo Alto, CA, USA). *J Appl Probab* v 24 n 2 Jun 1987 p 495-510.

**085556 SOJOURN TIMES IN QUEUEING NETWORKS WITH MULTISERVER MODES.** This paper generalizes previous results for sojourn-time distribution along so-called overtake-free routes in product-form networks of queues. (Author abstract) 25 refs.

Schassberger, R. (Technische Univ Berlin, Berlin, West Ger); Daduna, H. *J Appl Probab* v 24 n 2 Jun 1987 p 511-521.

**085557 NOTE ON WAITING TIMES IN SYSTEMS WITH QUEUES IN PARALLEL.** Numerical data are presented concerning the mean and the standard deviation of the waiting-time distribution for multiserver systems with queues in parallel, in which customers choose one of the shortest queues upon arrival. Moreover, a new numerical method is outlined for calculating state probabilities and moments of queue-length distributions. This method is based on power series expansions and recursion. It is applicable to many systems with more than one waiting line. (Author abstract) 2 refs.

Blanc, J.P.C. (Delft Univ of Technology, Neth). *J Appl Probab* v 24 n 2 Jun 1987 p 540-546.

**085558 REDUCING THE CONGESTION IN A CLASS OF JOB SHOPS.** Consider a job shop that is modeled as an open queueing network of the J.R. Jackson type. All work stations in the shop have the same number of parallel servers. Two problems are studied: the loading of stations and the assignment of servers, which are represented by loading and assignment vectors, respectively. Majorization and arrangement orderings are established to order, respectively, the loading and the assignment vectors. It is shown that reducing the loading vector under majorization or increasing the assignment vector under arrangement ordering will reduce the congestion in the shop in terms of reducing the total number of jobs. The results can be used to support production planning in certain job shops, and to aid the design of storage capacity. (Edited author abstract) 14 refs.

Yao, David D. (Harvard Univ, Cambridge, MA, USA); Kim, S.C. *Manage Sci* v 33 n 9 Sep 1987 p 1165-1172.

**085559 OPTIMAL SERVER ALLOCATION IN A SYSTEM OF MULTI-SERVER STATIONS.** Consider a closed queueing network with a set of stations. The service rate at each station is an increasing concave function of the number of jobs at that station. Suppose there also exists a station that has  $c$  ( $\geq 1$ ) parallel servers, each of which has a fixed service rate. We show that the throughput of this network is an increasing concave function with respect to  $c$ . This result is then applied to solve the optimal server allocation problem in a system of multi-server stations with a fixed buffer capacity (for the total number of jobs) at each station. For a single-station system, the simultaneous optimal allocation of both servers and buffer capacity is also studied. (Edited author abstract) 10 refs.

**085560 SIMULATING GI/G/k QUEUES IN HEAVY TRAFFIC.** This paper proposes a new consistent estimator for the expected waiting time in queue in the simulation of a multiserver queueing system. This estimator is called the 'error estimator' because it estimates only the error involved in the use of Kingman's heavy traffic approximation. Not only does this estimator retain all the advantages of the regenerative method, but it also reduces the variance of the estimator substantially when the traffic becomes heavy. (Author abstract) 10 refs.

Minh, Do Le (California State Univ, Fullerton, CA, USA). *Manage Sci* v 33 n 9 Sep 1987 p 1192-1199.

**085561 SOJOURN TIME DISTRIBUTIONS FOR THE M/M/1 QUEUE IN A MARKOVIAN ENVIRONMENT.** The author a single server queue in which both the arrival rate and service rate depend on the state of an external Markov Process (called the environment) with a finite state space. Given that the environment is in state  $j$ , the mean arrival and service rates are  $\lambda_j$  and  $\mu_j$  respectively. For such a queue, the queue length distribution is known to be matrix geometric. In this paper, we characterize the Laplace-Stieltjes transform of the sojourn time distribution under four disciplines - last come first served preemptive resume, last come first served, processor sharing and round robin. We also discuss a potential application of this queue in the area of data communication. (Edited author abstract) 11 refs.

Sengupta, Bhaskar (AT&T Bell Lab, Holmdel, NJ, USA). *Eur J Oper Res* v 32 n 1 Oct 1987 p 140-149.

**085562  $\Sigma \text{GI}[X_i]/M/S/K$  QUEUES WITH MIXED BATCH RENEWAL INPUTS.** This paper presents the analysis for the finite capacity queueing model with two independent mixed batch renewal inputs. The analysis is presented for the steady-state distribution at an arbitrary time and the steady-state distribution immediately before the arrival for each type of customers. The results can be applied to the models of various kinds of strategies such as delay-delay, delay-loss and loss-loss. Several examples are presented in order to discuss the effects of the interarrival distribution and the batch-size distribution on the individual blocking probabilities. (Edited author abstract) 17 refs.

Machihara, Fumiaki (NTT, Musashino, Jpn). *Electron Commun Jpn Part 1* v 70 n 9 Sep 1987 p 78-86.

**085563 DISCRETE PRIORITY QUEUEING SYSTEMS.** The author considers a single-service queueing system (QUS) with an infinite queue. It is assumed that any changes in the QUS take place at equidistant isolated instants of time  $t_j - 0$ ,  $t_j - t_{j-1} = t$ . The random variables  $(RV) \eta$  which is the interval between the instants of arrival of calls in the QUS, and  $\mu$  which is the service time of calls, have mesh distributions. In the case of simultaneous arrival of a bundle of calls in the QUS, it is assumed that all sorts of orders of service of the calls of the bundle are equally likely. Results show that input flow is a discrete counterpart of a very simple flow. Polaczek-Khinchin formulas for such systems are found to be similar to the formulas for the corresponding continuous systems. (Edited author abstract) 6 refs.

Ivanovskii, V.B. *Autom Remote Control* v 48 n 4 pt 1 Apr 1987 p 452-458.

**085564 QUEUEING NETWORKS WITH SYMMETRIC STANDBY CHANNELS.** A necessary and sufficient condition for representability of the equations of equilibrium in the product form is proven for open Markov queueing networks with two symmetric standby channels at the nodes. A stationary distribution of the probabilities of the states is found for analogous closed networks. The characteristics of the flows issuing from the network are investigated. (Author abstract) 12 refs.

**085565 EXACT ANALYSIS OF ROUND-ROBIN SCHEDULING OF SERVICES.** A multi-queue, cyclic-service model with a single-message buffer is considered. Each message consists of a number of characters, and one character is served at the server's each visit. Exact and explicit expressions are derived for performance measures, such as mean cycle time, mean message response time, and mean response time conditioned on the message length. (Edited author abstract) 14 refs.

Takagi, Hideaki. *IBM J Res Dev* v 31 n 4 Jul 1987 p 484-488.

**085566 THROUGHPUT RATE OF THREE-STATION PRODUCTION LINES: A UNIFYING SOLUTION.** A three-station production line with a Laplace transformable distribution of service time of the middle station and phase-type distribution of service times of the two outside stations is treated. A general formula for the throughput rate is derived. In this formula a system of linear equations with the number of equations equal to the number of stages of the service time of the last station needs to be solved. For some special cases, this formula reduces to simple expressions. (Author abstract) 12 refs.

**085567 EFFECTS OF SKEWNESS AND KURTOSIS OF PROCESSING TIMES IN UNPAID LINES.** Numerous empirical studies have shown that, in unpaid lines, the stations' processing times have a variety of shapes (i.e., skewness and kurtosis). This paper investigates how the line's utilization factor is affected by these skewness and kurtosis measures. We found that positive skewness has a significant negative effect on utilization, and that the magnitude of this effect is greater if the line has more stations or less buffer capacity, or if the processing-times' cv is larger. Kurtosis also affects utilization significantly, but the effect may be negative or positive, depending upon the processing-times' skewness and the number of stations in the line. (Edited author abstract) 23 refs.

**085568 SOFTWARE PACKAGE FOR THE QUEUEING SYSTEM  $M^x / G / 1$ .** A user-friendly software package, which should be found useful by researchers, practitioners and students alike, for the bulk-arrival single-server queueing system  $M^x / G / 1$  is discussed. It finds numerically the steady-state probabilities and moments for the number in the system at each of the three time epochs (pre-arrival, post-departure and random). It also finds the moments for waiting time in queue and busy and idle periods. (Author abstract) 2 refs.

**085569 ON THE  $\langle m, n(M^-/M^-) \rangle$  PRIORITY QUEUES AND THEIR APPLICATIONS.** We deal with a heterogeneous double finite-source priority model under the assumption that the priority group has preemptive priority over the ordinary one. In each source the units are characterized by exponentially distributed random variables with multiple parameters. The units are served by a single server according to first-in, first-out (FIFO), preemptive resume (PR) and priority processor sharing (PPS) service disciplines. The aim of the present paper is to give the main steady-state characteristics of the system, such as server's utilization, expected busy period length, mean sojourn and delay times, average number of customers staying at the service facility. As an application we consider the machine interference problem and show how this model can be used for the mathematical description of multiprogrammed computer systems. (Edited author abstract) 9 refs.

**085570 ANALYSIS OF THE QUEUE LENGTH AND THE OUTPUT FLOW IN SINGLE SERVER WITH FINITE WAITING ROOM AND PHASE TYPE DISTRIBUTIONS.** A single server queueing system with a buffer of finite capacity is considered. The interarrival times of customers and their service times are distributions of phase type (PH-distributions). The relations for binomial moments of stationary queue length distribution at the arbitrary instants of time as well as at the instants of customer arrival and service completion are obtained. The Laplace-Stieltjes transforms of waiting time distribution for the discipline FIFO and interdeparture times distribution are determined. (Author abstract) 11 refs.

**085571 NON-PREEMPTIVE PRIORITY QUEUE WITH SERVER'S WALKING PROCESS.** This paper considers the non-preemptive priority queue with the server's walking process. The state probability of the queue at the arrival of the server is derived from the generating function for the joint probability of the numbers of jobs with various priorities. Then the jobs are partitioned into two classes. The generating function for the number of jobs with higher priority is derived from which the queue waiting time is determined as one of the important evaluation measures of the queue system. The results in this paper can be applied to the performance evaluation of the simplified model for the data transmission system, TSS system and LAN. 8 refs.

**085572 QUEUEING SYSTEM WITH SERVER'S WALKING-TIME AND SERIAL SERVICE.** This paper considers two queueing systems with the server's walking process, where the service of the job is composed of more than one serial process. The first system is the scheme where the server arriving at the station serves in the last service stage for a job. The second system is the scheme where the server arriving at the station can serve more than one service-stage from the last to the first stage in the reverse order. When a job goes through a service at a certain stage, either it proceeds to the next service stage or leaves the system, following a specified probability. For both systems, the case of three serial stages in the stationary state is considered where the service time and the walking time follow general distributions. (Edited author abstract) 12 refs.

**085573 INFINITE CHANNEL QUEUEING SYSTEM WITH CONTROLLED INPUT.** The authors study a queueing model with a nonrecurrent input. The intensity of the input stream is regulated at epochs of successive starts of customers moving from the source to the system, and it is dependent on the number of busy channels. We consider three groups of channels. Such a division is connected with different expenditures of servicing within each of the groups. It is worthwhile to control the input rates in order to minimize the long-run average cost. The basic process is the number of busy channels. We derive its limiting distribution explicitly by introducing an auxiliary two-dimensional Markov process and treating the corresponding Kolmogorov system of differential equations. We also use some properties of semiregenerative processes. This limiting distributions are used to solve an optimization problem. (Edited author abstract) 8 refs.

**085575 GENERALIZED EXPANSION METHOD FOR OPEN FINITE QUEUEING NETWORKS.** Blocking makes the exact analytical analysis of open queueing networks with finite capacities intractable except for very small networks, therefore, approximation approaches are needed to analyze these types of networks. For exponential open finite queueing networks, some methods have been proposed but little has been done so far on nonexponential open finite queueing networks. This paper introduces a new approximation technique for the analysis of general open finite queueing networks. Extensive numerical examples are performed for different network topologies and the results are compared with simulation. (Author abstract) 37 refs.

**085576 MULTIQUEUE SYSTEM WITH NON-EXHAUSTIVE CYCLIC SERVICE MODELED AS A LINEAR-PROGRAMMING PROBLEM.** This paper shows how one important parameter can be estimated quickly, namely the cycle-time distribution. This is the distribution of times taken for the cyclic server to perform one complete cycle in its continuous scan of a number of queues. The method of solution is to identify various constraints which will determine the cycle-time distribution, formulate them as linear inequality and equality constraints and, by determining an appropriate objective function, apply the simplex method to find upper and lower bounds on the values taken by the cycle-time distribution itself. A great strength of this technique is its overall simplicity, which enables it to be used to obtain important results very quickly and cheaply. (Edited author abstract) 4 refs.

**085577 STRONG CONVEXITY RESULTS FOR QUEUEING SYSTEMS.** We prove a strong (and seemingly odd) result about the  $M/M/c$  queue: the reciprocal of the average sojourn time is a concave function of the traffic intensity. We use this result to show that the average itself is jointly convex in arrival and service rates. The standard deviation has the same properties. Also, we determine conditions under which these properties are exhibited by a standard approximation for the  $M/G/c$  queue. These results are useful in design studies for telecommunications and production systems. (Author abstract) 21 refs.

**085580 ANALYSIS OF MODELS REDUCIBLE TO A CLASS OF DIFFUSION PROCESSES IN THE POSITIVE QUARTER PLANE.** This paper is concerned with the two-dimensional generalization of the single server queue 'diffusion approximation'. This single queue approximation is based on a continuous representation of the discrete process of the number of jobs in the system, but differs by the type of boundary condition which is used. The state space of this continuous model is the positive real axis and the boundary is the zero of the real axis. The boundary condition consists here of an absorption and a sojourn on the boundary, followed by a jump back into  $R^+$ . This model describes within the same framework such phenomena as coupling of processors or simultaneous arrivals of jobs which do not preserve the classical 'product form' solutions. First we exhibit a pathwise construction of the process which leads to the existence, the uniqueness and the Markov property. From this, we derive a functional equation for the Laplace transform of the steady state distribution. The solution of this functional equation is obtained by reduction to a boundary value problem on the right branch of a hyperbola. Accordingly, these Laplace transforms are given as Cauchy type integrals since the conformal mapping of the infinite domain inside this right branch onto a disc is known in closed form. Finally, we propose a method for establishing the conditions ensuring the existence of the steady state distribution. (Edited author abstract) 14 refs.

**085581 STATIONARY DETERMINISTIC FLOWS: II. THE SINGLE-SERVER QUEUE.** The goal of this paper is to establish fundamental properties of queueing systems. A single-server queue is considered in which the usual probabilistic assumptions are not assumed to hold. Only the existence of long-term averages of inter-arrival times and service times is assumed. Based on the minimal assumptions, stability conditions are established. The asymptotic behavior of the unstable queue is determined. In addition, an investigation of the stable queue is undertaken. Topics include queues with failures and asymptotic birth-and-death equations. (Author abstract) 6 refs.

**085582 MULTISERVER QUEUES WITH SYNCHRONOUS FLUCTUATION OF TRAFFIC INTENSITY.** A study is presented on the generalization of the M/M/1 model with synchronous fluctuation of traffic intensity for the case of more than one server. The parameters of the queueing system fluctuate between two phases and the phase process is assumed to make changes according to an irreducible Markov chain. Phase changes may occur only when a customer arrives to the queue; his service time is also determined at his arrival instant, we compare our results to that of the asynchronous one and the comparison shows that we can approximate the performance of the asynchronous model by that of the synchronous one and vice-versa. However, we point out that to extend the M/M/K (M/M/ $\infty$ ) model with fluctuating parameters to the case of general inter-arrival, service, or sojourn time distribution, is easier in the synchronous model than in the case of the asynchronous one since the latter introduces considerable analytic complications. Two models, the M/M/K and M/M/ $\infty$ , with synchronous fluctuation of parameters are analyzed. Explicit results for the expected queue length are dis-

cussed. (Edited author abstract) 10 refs.

**085584 IMPACT OF THE COMPOSITION OF THE CUSTOMER BASE IN GENERAL QUEUEING MODELS.** We consider general queueing models dealing with multiple classes of customers and address the question under what conditions and in what (stochastic) sense the marginal increase in various performance measures, resulting from the addition of a new class of customers to an existing system, is larger than if the same class were added to a system dealing with only a subset of its current customer base. Our results enhance our understanding of the dependence of various performance measures with respect to the composition of the customer base. In addition they translate readily into convexity results in an (appropriately defined) arrival rate. (Author abstract) 25 refs.

**085585 CONVEXITY OF A GENERAL PERFORMANCE MEASURE FOR MULTISERVER QUEUES.** This paper examines a general performance measure for queueing systems. This criterion reflects both the mean and the variance of sojourn times; the standard deviation is a special case. The measure plays a key role in certain production models, and it should be useful in a variety of other applications. We focus here on convexity properties of an approximation of the measure for the M/G/c queue. For  $c \geq 2$  we show that this quantity is convex in the arrival rate. Assuming the service rate acts as a scale factor in the service-time distribution, the measure is convex in the service rate also. (Author abstract) 13 refs.

**085586 CONVEX ORDERING OF SOJOURN TIMES IN SINGLE-SERVER QUEUES: EXTREMAL PROPERTIES OF FIFO AND LIFO SERVICE DISCIPLINES.** The extremal properties of the ergodic sojourn times in G/G/1 queues under various service disciplines are studied in terms of the convex ordering. It is shown that among work-conserving non preemptive service disciplines that are service time independent, the FIFO and the LIFO service disciplines provide the minima and the maxima, respectively, of the ergodic sojourn times for any G/G/1 queue. For G/M/1 queues, this class of work-conserving service disciplines is extended to include preemptive/resume disciplines. (Author abstract) 7 refs.

**085590 ANALYTICAL APPROXIMATION TO THE QUEUEING MODEL:  $(HE_3/HE_3/1): (GD/\infty/\infty)$  FOR MAINTAINABILITY.** A queueing model,  $(HE_3/HE_3/1): (GD/\infty/\infty)$ , justified from a machine maintenance problem is investigated. This model defines both the interarrival times and service times as the hyperexponential distributions with three branches. This non-Poisson queueing model is considered as an alternate queueing system consisting of three separate stages, each of which is a Poisson queue. Therefore, the conventional analytical approach to a Poisson queueing model can be applied. Accomplishments of this study include constructing the flow rate diagram, setting up the state balance equations for acquiring queueing statistics, and employing the Gauss-Siedel numerical approach to obtain an analytical solution. (Author abstract) 4 refs.

**085591 CHARACTERIZATIONS OF EQUILIBRIUM QUEUE LENGTH DISTRIBUTIONS IN M/GI/1 QUEUES.** In certain multiqueue systems, a resourceful server may decide on which queue to attend to next based on critical that may include the equilibrium queue lengths of some or all queues. The server's decision will be unaffected by queue length only when the distribution of queue length is uniform. In studying this problem, we present first the simple case of the M/GI/1 queue to determine conditions under which equilibrium queue lengths can either be uniformly distributed, or have components that are uniform, and also present a method for designing such a queueing process. It is shown that there is an inherent connection between probability distributions  $\{k_j\}$  of the number of arriving customers during a service that are geometric, and equilibrium queue length distributions  $\{p_j\}$  that are geometric. In particular, we present a simple probabilistic proof via a recurrence equation that says that the M/M/1 queue is the only M/GI/1 queue with both  $\{k_j\}$  and  $\{p_j\}$  geometric. (Author abstract) 7 refs.

**085592 ANALYSIS OF QUEUEING SYSTEMS WITH RANDOMLY CHANGING POPULATION STATES.** The queueing system, in which the property of the population is changing randomly, frequently is observed in various problems, and it is important to know its property. However, the analysis of the characteristics of such a system in general is difficult. From such a viewpoint, this paper considers the simplest example of the M/M/1 system, where the inter-arrival-time distribution or service-time distribution changes following a two-stage Markov chain. A strict solution is derived for the behavior of the system. Using the state-transition rate diagram of the system, the system equation for the steady-state is derived. Then the z-transform of the steady-state probability distribution and the Laplace transform of the waiting time distribution are obtained. (Edited author abstract) 4 refs.

**085601 ESTIMATES OF THE STABILITY OF QUEUEING PROCESSES.** This paper is devoted to estimates of the ability of the distributions of discontinuous functionals of queueing processes under disturbances of the distribution functions of the input data. The estimates are made under some assumptions which ensure continuity of these functionals with probability 1 with respect to the undisturbed distribution of the input. (Author abstract) 3 refs.

Logunov, P.L. *Sov J Comput Syst Sci* v 25 n 4 Jul-Aug 1987 p 182-184.

**085602 TWO-PHASE QUEUEING SYSTEM WITH MULTIPLICATIVE DISTRIBUTION OF THE STATIONARY PROBABILITIES.** The solution for a stationary distribution of the state probabilities in multiplicative form is obtained for a two-phase queueing system with supplementary flow into the second phase and with a dependence of the service in the first phase on service in the second. The system is subject to Poisson input flows and exponential service laws. (Author abstract) 4 refs.

Gromov, A.I. *Sov J Comput Syst Sci* v 25 n 4 Jul-Aug 1987 p 184-186.

**085603 DISTRIBUTION OF THE SUPREMUM OF THE QUEUE LENGTH IN QUEUEING SYSTEMS WITH POISSON INPUT FLOW.** A single-server queueing system with a nonordinary Poisson input flow is examined. The durations of orders service are independent but not necessarily identically distributed. The distribution of the supremum of the queue length is obtained. (Author abstract) 8 refs.

Abramov, V.M. *Sov J Comput Syst Sci* v 25 n 4 Jul-Aug 1987 p 189-193.

**085604 APPROXIMATION OF KNOWN ACCU-**

**RACY FOR SINGLE SERVER QUEUES WITH INHOMOGENEOUS ARRIVAL RATE AND CONTINUOUS SERVICE TIME DISTRIBUTION.** A practical method for obtaining approximate results for single server queues with inhomogeneous queues and continuous service time distribution is presented. The method is based on a discrete approximation to the continuous service time distribution. Exact results can be obtained for the corresponding queueing system with discrete service time distribution. These results are then corrected, and the likely accuracy of the corrected results is estimated. Four measures of performance are considered, idleness probability, mean and variance of number of customers in the system and virtual waiting time. (Author abstract) 7 refs.

**085608 VERTEX-ALLOCATION THEOREM FOR RESOURCES IN QUEUEING NETWORKS.** A product-form queueing network with multiple open and closed chains is considered. Some of the closed chains, which have a single customer each, require allocation of resources in the network so as to maximize a weighted

throughput performance criterion. Chains with more than one customer can be decomposed into many chains of one customer each. It is proved that an optimal allocation of resources lies on a vertex (extreme points) of the set of feasible allocations. This considerably reduces the search space for an optimal allocation. Applications of this result in distributed computing are discussed. (Author abstract) 15 refs.

**085609 PERFORMANCE EVALUATION OF A FINITE QUEUE WITH RANDOM ROUTING.** In previous papers, the steady-state behavior of a finite queue which accepts batch Poisson inputs and receives service operating in the synchronous mode was studied. Analysis was successfully completed via the application of the Residue theorem in complex variables. This paper extends the work to include the effect of routing. Two types of random routing are considered in this paper. Results obtained include state-transition probability, blocking probability, delay, and throughput. The validity of analysis has been verified by computer simulation. (Author abstract) 6 refs.

**085613 STOCHASTIC MONOTONICITY OF THE QUEUE LENGTHS IN CLOSED QUEUEING NETWORKS.** We study a Gordon-Newell type of closed queueing network that frequently arises in modeling manufacturing and computer systems. We are concerned with the transient and equilibrium behavior of the joint and individual queue lengths in the network when the job population increases. We show that increasing the job population will stochastically increase the queue-length vector process, provided that all stations have nondecreasing service rates. Single and multivariate likelihood ratio orderings are also established for the joint queue lengths in equilibrium. Our results extend the applicability of previously known results in the literature. (Author abstract) 15 refs.

**085614 SIMPLE INEQUALITIES FOR THE D/G/1 QUEUE.** We present a new method for obtaining bounds for the stationary D/G/1 queue. The basic idea is to translate crude bounds on the probability that the system is empty at time  $t$  into sharp bounds for the expected waiting time. The crudest possible bounds on the probability that the system is empty at time  $t$  reproduce the Kingman upper bound and the Marshall lower bound, and show that the Marshall lower bound is tight for the D/G/1 queue and is attained if and only if the service times are integer (random) multiples of the interarrival time. (Edited author abstract) 23 refs.

**085616 FINITE-SOURCE QUEUEING MODEL FOR SOME MANUFACTURING PROCESSES.** The paper is concerned with a finite-source queueing model which can be applied in the field of manufacturing economics. Different types of highly reliable machines are supervised by a single robot which supplies them with raw materials in random order. The production time of machine  $i$  is supposed to be an arbitrarily distributed random variable having density function  $f_i(x)$ ,  $i = 1, \dots, n$ , while the service times are assumed to be identically and exponentially distributed random variables. This paper gives the main steady-state operational characteristics of the system, such as utilizations, average number of idle machines, and mean waiting times of the machines. A cost function is considered which measures the total loss of the system per unit time. (Edited author abstract) 15 refs.

Sztrik, J. *Probl Control Inf Theory* v 16 n 6 1987 p 449-457.

**085617 HEAVY TRAFFIC LIMIT OF A CLASS OF MARKOVIAN QUEUEING MODELS.** Reflected Brownian motion is obtained as the heavy traffic limit of the level component of a class of bivariate Markov chains incorporating those having a matrix-geometric stationary distribution. Approximations for both transient and ergodic behavior are obtained as a corollary and illustrated for the Markov-modulated queue. The result is stated and proven. Once this has been established, approximations for a number of relevant characteristics then come out as corollaries. (Edited author abstract) 14 refs.

**085618 INCLUSION OF STORAGE IN A QUEUEING SYSTEM.** Service operations involving an intermediate store are modelled using an extended definition of the system state which is a conventional definition of state supplemented with an indicator of the live capacity in the store. Additional to the parameters of mean service rate and mean arrival rate, a mean discharge rate of the store is introduced and the steady state probabilities are calculated in terms of these three quantities. Both finite source and infinite source cases are considered under the assumption of exponential distributions. The models permit production comparisons for systems with and for systems without storage devices. (Author abstract) 5 refs.

**085619 ON MULTISERVER QUEUES WITH**

**m-PHASE SYNCHRONOUS FLUCTUATION OF TRAFFIC INTENSITY.**  $M^{(m)}/M/K$  and  $M^{(m)}/M/\infty$  models with synchronous fluctuation of traffic intensity are considered. The phase process is assumed to make changes according to an irreducible m-phase Markov chain. In contrast to the model with asynchronous fluctuation of parameters, phase changes may occur in synchronization with an arrival or beginning of a customer's service. We study mainly the steady-state regime of our models, and observe that, in general, closed form solutions for the limiting probabilities are difficult to obtain but their numerical computation straightforward. We give a necessary and sufficient condition for the steady-state to be attained. For the model  $M^{(d)}$  considered which measures  $m/M/K$ , it is shown that, for the case where the traffic intensity of one phase is greater than one, the average queue length approaches infinity as the fluctuations among phases gets more sluggish. However, for the case where the traffic intensity for all phases is less than one, the queue length is moderate and not dependent as much on the rate of fluctuation among phases. Numerical examples are given and discussed. We point out that our models may be more tractable than the asynchronous ones, when we try to generalize them to the case of general inter-arrival, service, or sojourn time distribution. (Edited author abstract) 14 refs.

**085620 QUEUEING ANALYSIS METHODS FOR MIXED LOSS AND DELAY SYSTEMS: EXACT AND DIFFUSION APPROXIMATION RESULTS.** This paper presents queueing analysis methods for mixed loss and delay systems. The queueing models considered are an extension of previously analyzed models and are applicable to the Facsimile Intelligent Communication System (FICS). Assuming compound Poisson arrivals and a single server, an exact result for performance measures of the model is obtained by the supplementary variable technique. Assuming general batch arrivals and many servers, a diffusion process approximation with the elementary return boundary is developed. A new recursive scheme for the steady-state distribution of the number of customers in the system is derived. Numerical examples are provided and compared with exact and simulated results, which demonstrate the accuracy of the approximation. (Edited author abstract) 29 refs.

**085622 ARRANGEMENT OF SERVERS IN AN ORDERED-ENTRY SYSTEM.** We consider a service system whose servers may work at different rates (systems with 'heterogeneous servers'). Jobs arriving at the system access the servers in accordance with an 'entry order' that relates to the arrangement of the servers. When all servers are occupied, arriving jobs are blocked and lost. This model has applications in the study of the conveyors and other circulation systems. We wish to compare various server arrangements in such systems. We represent the arrangement of servers by a permutation vector of their service rates, and develop a partial order on these vectors.

By moving in the direction pointed out by this partial order, one can reduce blocked traffic, thereby improving system performance. (Edited author abstract) 14 refs.

**085624 MAXIMUM ENTROPY ANALYSIS OF THE G/G/1 QUEUE AT EQUILIBRIUM.** The principle of maximum entropy is used to analyze a G/G/1 queue at equilibrium when the constraints involve only the first two moments of the interarrival-time and service-time distributions. Robust recursive relations for the queue-length distribution are determined, and a probability density function analog is characterized. Furthermore, connections with classical queueing theory and operational analysis are established, and an overall approximation, based on the concept of 'global' maximum entropy, is introduced. Numerical examples provide useful information on how critically system behavior is affected by the distributional form of the interarrival and service times, and favorable comparisons are made with diffusion and other approximations. (Edited author abstract) 38 refs.

**085626 APPLICATION OF LITTLE'S RESULT TO THE G/G/1 (LCFS/P) QUEUE.** This paper considers a quite general single-server queueing system, under a last-come-first-served queue discipline, with pre-emption and arbitrary restarting policy. Expressions are given for the queue-size limiting distribution when the system is considered at arrival (or departure) epochs and in continuous time, by using very simple arguments. The service system is such that customers arrive at a service station at certain epochs in accordance with a stationary point process of rate. There is a single server and waiting facility for infinitely many customers. The service times of the successive arriving customers form a stationary process. Hence, these are identically distributed but not necessarily independent random variables, with a mean by which is assumed to be finite. The arrival process and the service times are stochastically independent. (Edited author abstract) 9 refs.

**085627 DESIGNING OF OPTIMUM QUEUES.** Recently the concept of  $\alpha$ -power—has been introduced into the flow control of computer communications networks. We have clarified the conception from the point of view of electrical network designs. Originally the word  $\alpha$ -power—was derived from a category of electrical circuit theory. There are three criteria for electrical network design: maximum voltage (voltage oriented)

technique, maximum current (current oriented) technique, and the maximum power (power oriented) technique. The last technique is more useful for design of audio amplifiers, transmission lines, and antennas. With such apparatus, there are two elements of power, i.e. power loss due to inner impedance and working power due to the effective resistance of the connection to the external world. Customers of a queueing system are forced to wait. This waiting is an disadvantage, and thus a loss. We regard the queueing system as being equivalent to an electrical circuit and have applied electrical circuit design techniques to queueing system design. All the power of the system, that is, the supplied power, the loss power and the working power has been automatically derived from the correspondence between a queueing system and an electrical circuit. **085632 APPROXIMATE ANALYSIS OF PRODUCT-FORM TYPE QUEUEING NETWORKS WITH BLOCKING AND DEADLOCK.** A numerical procedure for analyzing exactly closed exponential queueing networks with finite queues is presented first. Due to the

finiteness of these queues, blocking and deadlock may occur. Deadlocks are assumed to be detected and resolved instantaneously. The numerical procedure is then incorporated in an approximation algorithm for analyzing closed exponential queueing networks of the product-form type, in which some of the queues are finite. These finite queues are assumed to be linked together to form a single subnetwork. The approximation algorithm is based on a variant of Norton's theorem. Comparisons between the approximate results and exact numerical results were carried out and the relative error was observed to be small. (Author abstract) 20 refs.

**085633 ALLOCATION OF SPACE BETWEEN SERVICE AND WAITING AREAS IN A SERVICE SYSTEM.** Service systems are concerned with provision of some form of treatment or accommodation to customers or to something belonging to the customers. Typically, service systems are comprised of two physically distinct areas, one dedicated to the service itself, the other used for customers waiting for service. A limited amount of space is available for the two purposes. This paper addresses a related problem of concern to designers and managing operators of service systems, namely how to divide a total available area among service units and waiting spaces. Under Poisson arrivals and exponentially distributed service times we develop an algorithm for choosing the number of service units and the number of waiting spaces so as to minimize the expected total costs per unit time. (Author abstract) 5 refs.

**085634 TANDEM QUEUE WITH FINITE INTERMEDIATE WAITING ROOM AND BLOCKING IN HEAVY TRAFFIC.** A two-stage exponential network with an unlimited first-state queue and a finite waiting room in the second stage are investigated. When the waiting room is full, the first-stage server is blocked and ceases to offer service. A request served by the second-stage server may return to the first-stage queue with a positive probability or leave the network. A limiting distribution of the steady-state queue lengths in heavy traffic is obtained explicitly. The queues are shown to be asymptotically independent. The first-stage queue behaves as an M/G/1 queue in heavy traffic, and the second-stage queue as an M/M/1/m queue. (Author abstract) 5 refs.

**085637 PERSPECTIVES ON QUEUES: SOCIAL JUSTICE AND THE PSYCHOLOGY OF QUEUEING.** Queueing environment and feedback regarding the likely magnitude of the delay can also influence customer attitudes and ultimately, in many instances, a firm's market share. Even if we focus on the wait itself, the 'outcome' of the queueing experience may vary nonlinearly with the delay, thus reducing the importance of average time in queue, the traditional measure of queueing performance. This speculative paper uses personal experiences, published and unpublished cases, and occasionally 'the literature' to begin to organize our thoughts on the important attributes of queueing. (Edited author abstract) 46 refs.

Larson, Richard C. (MIT, Cambridge, MA, USA). *Oper Res* v 35 n 6 Nov-Dec 1987 p 895-905.

**085638 PERSPECTIVES ON QUEUES: COMBINING QUEUES IS NOT ALWAYS BENEFICIAL.** There are significant reasons for believing that combining queues may at times not be a good thing to do. These reasons include customer reaction, elimination of jockeying, increased service times and costs for combined queues, and the absence of published before-and-after studies. It is hoped that when operations researchers think about and analyze service systems, they will pay attention to the concerns raised. In addition, it is hoped that some of these concerns will inspire new research on queueing questions and will encourage publication of careful reports of experience in combining queues in counter service systems. 21 refs.

**085639 MEAN VALUE ANALYSIS APPROXIMATION FOR MULTIPLE SERVER QUEUEING NETWORKS.** An approximation of mean value analysis is presented for queueing networks containing multiple server stations. The approximation is based on the estimation of the conditional marginal probabilities used by the mean residence time formula in mean value analysis. A comparison against classical mean value analysis allows us to determine the accuracy of our algorithm. In all investigated network models, the approximate results vary from the exact results by less than four percent on the average. This approximation method has the advantages of classical mean value analysis; specifically, it is easy to implement and has a short run time. (Edited author abstract) 21 refs.

**085640 ANALYSIS OF SYMMETRIC POLLING SYSTEMS WITH TWO PRIORITY CLASSES.** A cyclic multiqueue system consists of several stations in which messages are enqueued for transmission, and which are served sequentially in cyclic order by a single server. The arrivals at each queue are independent Poisson processes, and the transmission times are generally distributed. There is a nonzero switchover time from one station to the next, which is also generally distributed. Messages can be at either of two priority levels: priority 1 (low) or priority 2 (high), and polling occurs either at low priority, in which case both priority 1 and priority 2 messages can be transmitted, or at high priority, in which case only priority 2 messages are transmitted. The service disciplines considered are the exhaustive service discipline and the gated service discipline. In both cases the performance, as measured by the expected delay for high- and for low-priority messages, is evaluated. Part of the analysis is approximate. (Edited author abstract) 20 refs.

**085644 NUMERICAL SOLUTION FOR THE DEPARTURE PROCESS FROM THE  $GI/G/1$  QUEUE.** The performance measures of a queue is depend on its input process. Hence, if the input process of a queue in the output process of another, this output process becomes important. For similar reasons, output processes are important in queueing networks. The purpose of this note is to present a numerical solution for the interdeparture-time distribution of the  $GI/G/1$  queueing system. We present efficient numerical procedures to determine the idle-time distribution of a  $GI/G/1$  queue. (Edited author abstract) 10 refs.

Jain, Joti L. (Univ of Delhi, Delhi, India); Grassmann, Winfried K. *Comput Oper Res* v 15 n 3 1988 p 293-296.

**085645 SIMPLE APPROXIMATIONS FOR THE  $GI/G/C$  QUEUE - I: THE STEADY-STATE PROBABILITIES.** Viewing the  $GI/G/c$  queue as a service system alternating between two basic states - that of a loaded (non-empty)  $GI/G/1$  queue and that of a  $GI/G/\infty$  queue (dependent, respectively, on whether all servers in the  $GI/G/c$  queue are busy or otherwise) - approximations for the components of the mixture distribution of the steady-state probabilities are derived. The  $M/G/c$  queue is separately treated. Two imposed prerequisites, that only minimal prior information about the queue will be required and that no numeric method be needed other than a root-finding algorithm, are strictly adhered to. The accuracy attained is generally satisfactory, while remarkable algebraic simplicity is preserved. (Author abstract) 20 refs.

Shore, Haim (Tel Aviv Univ, Isr). *J Oper Res Soc* v 39 n 3 Mar 1988 p 279-284.

**085646 EXTREME VALUES OF QUEUE LENGTHS IN  $M/G/1$  AND  $GI/M/1$  SYSTEMS.** We study the limiting behavior of maximum queue lengths in the  $M/G/1$  and  $GI/M/1$  service systems. When the systems are positive recurrent, the distributions of their maximum queue lengths, under standard linear normalizations, either do not converge or they converge to degenerate limits. Consequently, one cannot use classical extreme value theory to characterize their limiting behavior. We show, however, that by varying the system parameters in a certain way as the time interval grows, these maxima do indeed have three possible limit distributions. Two of them are classical extreme value distributions and the third one is a new distribution. The latter distribution is the best one for practical approximations. (Author abstract) 9 refs.

**085647 APPROXIMATION METHOD FOR TANDEM QUEUES WITH BLOCKING.** Our approach relies on the use of marginal probability distributions ('state equivalence') coupled with an approximate evaluation of the conditional probabilities introduced through the equivalence. The method iterates over consecutive pairs of servers using the solution of a two-queue system as a building block. It produces performance measures for individual servers as well as an approximation to joint queue-length probability distributions for pairs of neighboring stations. Experience indicates that the number of iterations required for the method grows moderately with the number of nodes in the network. We give examples to demonstrate the accuracy and the convergence properties of the proposed approximation. (Edited author abstract) 20 refs.

**085648 SAMPLE PERFORMANCE FUNCTION OF CLOSED JACKSON QUEUEING NETWORKS.** We study a sample performance function of a closed Jackson queueing network; specifically, the time required by a server to serve a finite number of customers. We show that this sample performance function is a continuous, piecewise linear function of the mean service time. We prove that the average of derivatives of this sample performance function with a given initial state does converge, with probability one, to the derivative of the conditional mean value, given the same initial state. The result shows that the estimate of the derivative of a server's mean throughput in a finite time period with respect to the mean service time obtained by infinitesimal perturbation analysis is strongly consistent. (Edited author abstract) 14 refs.

**085649 SIMPLE APPROXIMATIONS FOR THE  $GI/G/C$  QUEUE - II: THE MOMENTS, THE INVERSE DISTRIBUTION FUNCTION AND THE LOSS FUNCTION OF THE NUMBER IN THE SYSTEM AND OF THE QUEUE DELAY.** Based on the results obtained in part I of this paper, approximations for the first four moments of the number in the system are developed and thence used to approximate the inverse distribution function (IDF) and the loss functions (LF), employing Shore's general approximations. Existing approximations for the first two moments of queueing time in a  $GI/G/1$  queue serve to approximate the IDF and the LF of queueing time in the corresponding  $GI/G/c$  queue. The accuracy attained is generally satisfactory, while a remarkable algebraic simplicity is preserved. A numerical example demonstrates the applicability of some of the new approximations to solve optimization problems. (Author abstract) 15 refs.

**085651 SOME THOUGHTS ON AN  $O(N^3)$ -ALGORITHM FOR THE OPTIMAL CONTROL OF ARRIVALS IN A GI/M/1/N QUEUE.** A formerly presented  $O(N^3)$ -algorithm for the optimal control of arrivals in a GI/M/1/N queue is extended for solving the problems with the average reward criterion and with a general action space. Details of the model are described where specific problems are formulated. This section considers a version of the control problem where the average reward per transition in the long run is to be maximized by choosing an appropriate customer acceptance/rejection rule. 3 refs.

**085655 MINISUM LOCATION OF A TRAVELING SALESMAN.** We deal with the problem of locating on a network a service unit that must visit all the calls that are registered in a service list. Each node can generate a call with a given probability and the service list contains the first  $b$  calls that have arrived  $b \leq n$  ( $n$  is the number of nodes). In our problem the optimal location minimizes the expected length of a traveling salesman tour (TST) traveled. For the problem which requires  $2^n$  calculations of probabilities, we develop an  $O(n)$  algorithm when  $b = n$ , for a tree, and study the sensitivity of this optimal solution when  $b < n$ . **085657 APPROXIMATE PRODUCT FORM FOR A CLASS OF DEGRADABLE QUEUEING NETWORKS.** An approximate product form for a class of degradable queueing networks (DQNs) is presented. DQNs emerge from a synthesis of separable queueing networks (BCMP networks) and the classical machine-repair-man mode. Under the assumption that failure and repair events which change the level of performance are less frequent compared with the service completions of tasks moving through the network, the presented product form approximates the exact probability distribution very closely. Because DQNs are near-completely decomposable, the error of approximation depends on the degree of coupling between the different modes of degraded performance. In accordance with the theory of near-complete decomposability, a numerical example shows that the approximation error is proportional to the degree of coupling. (Edited author abstract) 22 refs.

**085658 AMVA PRIORITY APPROXIMATION.** Most computer systems contain one or more system resources whose usage is controlled on the basis of workload priorities. Unfortunately, the exact analysis of queueing network models incorporating priority scheduling disciplines is usually infeasible. The MVA Priority Approximation has been proposed as a comparatively inexpensive, and yet reasonably accurate, approximation technique for queueing networks with priority scheduled service centers. Even this algorithm, however, is too expensive to apply to large networks with many classes of customers. We show how the MVA Priority Approximation can be modified so that it utilizes approximate rather than exact Mean Value Analysis (MVA), without significant loss of accuracy. Numerical experiments are performed to further assess the accuracy of the modified algorithm, termed the AMVA Priority Approximation. These experiments utilize the parameter space mapping technique for studying 'local' queueing network approximations. (Edited author abstract) 20 refs.

**085659 NEW MVA-BASED APPROXIMATION FOR CLOSED QUEUEING NETWORKS WITH A PREEMPTIVE PRIORITY SERVER.** We propose a new MVA-based noniterative algorithm for solving closed queueing network models of computer systems with a preemptive priority server. The algorithm attempts to capture synchronization error, delay error and the effect of preemption on the interarrival time variability of lower priority jobs at FCFS servers, but also at other servers in the system. Numerical results indicate that the algorithm predicts the performance measures of low priority jobs more accurately than previously developed MVA-based algorithms. (Author abstract) 25 refs.

**085660 ON SERVER ALLOCATION IN MULTIPLE CENT MANUFACTURING SYSTEMS.** The

problem is formulated as a nonlinear integer program of allocating servers in a closed queueing network to maximize throughput. We show that the throughput of the closed queueing network has a monotonicity property, such that any optimal allocation must give more servers to stations with a higher workload. The number of allocations that satisfy this property is much smaller than the total number of feasible allocations. This property and a bounding technique for the throughput of the closed queueing network are combined to develop a search algorithm to obtain an optimal allocation of servers. A greedy heuristic is also developed, and its optimality proven in the special case of a two-center system. (Edited author abstract) 19 refs.

**085662 SYSTEMS WITH HIDDEN SERVICING UNDER CONDITIONS OF A HEAVY LOAD. I.** A study is made of a queueing system consisting of a single device that receives a flow of orders, each of which leaves the system at the end of some random interval that is independent of the servicing process and that began at the instant of arrival of the order. This interval is called the lifetime of the order. The servicing device moves along a queue, allotting for each order a random time - a servicing quantum. The situation of a heavy load is investigated; that is, it is assumed that the lifetime is much greater than the duration of a service quantum and the average interval between arrivals in the system. Three types of motion of the device are examined: forward motion, from the beginning to the end of the queue, inverse motion, from the end to the beginning, and shuttle motion, from the beginning to the end of the queue and back. Limiting distributions are obtained for the number of times orders appearing in the system are serviced in a stationary regime. (Author abstract) 2 refs.

**085666 OPTIMAL DESIGN OF MULTISERVER QUEUEING SYSTEMS WITH DIFFERENT WAITING COSTS FOR TIME IN QUEUE AND TIME IN SERVICE.** The optimal number of servers and service rate are characterized for multiserver systems in which waiting times in service and in queue have different costs. It is shown that the optimal choice of the service rate and the number of servers depends on the ratio of the in-service waiting cost coefficient to the in-queue waiting cost coefficient. For M/M/c systems, a single server is optimal if the cost-coefficient ratio exceeds a threshold value of one-half. For GI/M/c and M/G/c systems, the threshold ratio increases as the variation of the interarrival or service time increases. (Author abstract). 12 Refs.

**085670 COMPUTERIZED CLOSE QUEUEING NETWORK MODELS OF FLEXIBLE MANUFACTURING SYSTEMS: A COMPARATIVE EVALUATION.** Advanced closed queueing network models are available for stochastic performance evaluation of Flexible Manufacturing Systems (FMS). These models are useful during the planning and design phases of FMS, since they can be applied to study gross tradeoffs between principal design parameters. This paper analyzes several computerized models for evaluating complex FMS facilities with respect to the desired allocation of the following key resources: manufacturing centers, transporters, pallets and tools. It focuses on such issues as the structure of the mathematical system models, the variety of performance measures (model outputs), model inputs, accuracy of results and computational effort. Original alternatives to overcome part of the common limitations of the models are developed and tested empirically. (Edited author abstract). 32 Refs.

**085671 ON EXTENDING THE SCOPE OF BOUNDING TECHNIQUES FOR CLOSE QUEUEING NETWORKS.** Queueing network models are widely used to analyze the performance of automated manufacturing facilities and computer systems. These models aid the designers/operators of the system in evaluating the impact of various alternate configurations on the performance of these systems. In many instances, however, the exact analysis of these networks for performance measures may not be necessary; some bounds on the performance measures may be adequate. This has motivated research on obtaining bounds on performance measures, and a number of techniques have recently been developed. These techniques have generally obtained bounds on the throughput for networks with a single class of customers, where each node is either a single server fixed-rate type or is a delay (infinite server) type. We extend the scope of these techniques to networks where non-delay nodes are allowed to have some service rates which depend on the number of jobs present at the nodes. Efficient means are developed for calculating bounds on the mean queue lengths forming at the nodes in these networks. (Edited author abstract). 21 Refs.

Srinivasan, M.M. (Univ of Michigan, Ann Arbor, MI, USA). *Large Scale Syst* v 12 n 2 1987 p 125-142.

**085672 SINGLE SERVER QUEUEING-LOCATION MODELS WITH REJECTION.** Calls from a node can either all be accepted or all be rejected by the service system. Two models are considered: a call can be rejected independently of the state of the system when the call arrives; an arriving call can be rejected only if it finds the server busy. The queueing systems are analyzed for both models. A greedy heuristic is developed which, parametrically in the arrival rate of calls, determines the location of the server and the rejection strategies at nodes. Extreme case analysis with respect to the arrival rate is investigated. Our major observation is that the rejection strategies for calls are dependent on the arrival rate and the choice of model. **085673 INTERPOLATION APPROXIMATION FOR QUEUEING SYSTEMS WITH POISSON IN-**

PUT. Heavy traffic limit theorems yield expressions for normalized quantities of interest. In light traffic, we can obtain, in addition to limits, more sensitive information by calculating what are effectively derivatives (of the quantity of interest) with respect to the arrival rate. We can then combine the light and heavy traffic results to yield a polynomial (in the arrival rate) as an approximation to the normalized quantity of interest. We present the details of the above approximation, focusing, via several examples, on applications of the method. We compare the results of the approximation, for the examples considered, with exact and simulation results. We compare our results to some related approximations. For the examples considered, the approximation works extremely well. (Edited author abstract). 10 Refs.

**085674 SIMPLE BOUNDS FOR FINITE SINGLE-SERVER EXPONENTIAL TANDEM QUEUES.** A new bounding methodology for nonproduct form systems is applied to the finite single-server exponential tandem queues. The methodology is based on modifying the original system into product form systems that provide bounds for some performance measure of interest. The product form modifications given for this finite tandem queue propose a computationally attractive and intuitively obvious lower and upper bound for the call congestion and throughput. Numerical results indicate that the bounds are reasonable indicators of the order of magnitude. This can be useful for quick engineering purposes as will be illustrated by an optimal design example. A formal proof of the bounds is given. (Edited author abstract). 32 Refs.

**085675 FURTHER REMARKS ON QUEUEING NETWORK THEORY.** Most attributions date the start of queueing network theory to a 1957 paper of J.R. Jackson entitled, 'Networks of waiting lines'. This paper has formed the basis of a considerable amount of work that has occurred since. This is reviewed so as to introduce the important idea of a Jackson network. The paper also considers three problem areas that seem to be those considered most often in current queueing network theory. The areas are: traffic processes; sojourn times; and queue lengths.

**085677 ON THE OVERFLOW PROCESSES FROM THE PH<sub>1</sub> + PH<sub>2</sub>/M/S/K QUEUE WITH TWO INDEPENDENT PH-RENEWAL INPUTS.** This paper presents an analysis of overflow processes from a PH<sub>1</sub> + PH<sub>2</sub>/M/S/K queue having two independent phase type renewal input streams. Both the superposed overflow process and individual overflow processes for the PH<sub>1</sub>- and PH<sub>2</sub>-streams are analyzed using first passage time distributions for the number of customers in the system. Each

overflow process is characterized as a Markov renewal process. The  $n$ th moment of the number of customers in an infinite server group to which these overflows have been offered is derived using a theory for the  $MR/M/\infty$  queue with a Markov renewal input. The numerical examples for means and variance-to-mean ratios (peakednesses) of the individual overflow streams are given for an  $H_2+H_2/M/S/S$  queue with interrupted Poisson inputs, which is a vital model for telephone network planning. Overflow traffic characteristics are discussed by using these examples. (Edited author abstract). 21 Refs.

**085678 ACCURACY, SPEED, AND CONVERGENCE OF APPROXIMATE MEAN VALUE ANALYSIS.** Approximate Mean Value Analysis (AMVA) is an approach to analyzing queueing network performance models because of the combination of efficiency, accuracy, and versatility that it affords. We present a new modification, termed the Aggregate Queue Length (AQL) algorithm, of the basic AMVA scheme for load-independent separable networks. AQL is more efficient than, and yet has apparently similar accuracy as, the most accurate of the AMVA algorithms previously known. We examine the question of convergence of AMVA techniques, and demonstrate that there are networks for which convergence occurs only extremely slowly. We propose a new stopping criterion that detects these cases, and an extrapolation technique for them that allows accurate solutions to be obtained quickly. (Edited author abstract). 22 Refs.

**085679 M/G/ $\infty$  WITH BATCH ARRIVALS.** Let  $p_{\infty}(n)$  the distribution of the number  $N(\infty)$  in the system at ergodicity for systems with an infinite number of servers, batch arrivals with general batch size distribution and general holding times. This distribution is of importance to a variety of studies in congestion theory and storage systems. To obtain this distribution, a more general problem is addressed. In this problem, each epoch of a Poisson process gives rise to an independent stochastic function on the lattice of integers, which may be viewed as stochastic impulse response. A continuum analogue to the lattice process is also provided. (Author abstract). 6 refs.

**085683 TWO PARALLEL M/G/1 QUEUES WHERE ARRIVALS JOIN THE SYSTEM WITH THE SMALLER BUFFER CONTENT.** Two parallel, infinite-capacity M/G/1 queues characterized by  $(U_1(t), U_2(t))$ , with  $U_i(t)$  denoting the unfinished work (buffer content) in queue  $i$  are considered. An arrival is assigned to the queue with the smaller buffer content. Asymptotic approximations to the joint stationary distribution of the Markov process  $(U_1(t), U_2(t))$  are constructed, treating separately the asymptotic limits of heavy traffic, light traffic, and large buffer contents. In heavy traffic, the stochastic processes  $U_1(t) + U_2(t)$  and  $U_2(t) - U_1(t)$  become independent; the distribution of  $U_1(t) + U_2(t)$  is identical to the heavy traffic waiting time distribution in the standard M/G/2 queue, and the distribution of  $U_2(t) - U_1(t)$  is closely related to the tail of the service-time density. In light traffic, a formal expansion of the stationary distribution in powers of the arrival rate is obtained. 12 refs.

Knessl, Charles (Northwestern Univ, Evanston, IL, USA); Matkowsky, Bernard J.; Schuss, Zeev; Tier, Charles. *IEEE Trans Commun* v COM-35 n 11 Nov 1987 p 1153-1158.

**085684 OPTIMAL CONTROL OF PREMATURE QUEUEING.** Given an M/G/1 queue, a special customer, and an exponential random variable  $M$  that is independent of the queueing process, if the special customer reaches the front of the queue before the time specified by  $M$ , it cannot be processed and must re-enter the queue at the back. While waiting in the queue, the available decisions for the special customer are either to keep its position in the queue or to leave its position to join the back of the queue. The author's goal is to find a strategy that minimizes the expected delay until the special customer starts being processed. The move-along policy is to always stay in the queue until the front of the queue is reached, and if it cannot be served, to join the back of the queue. The basic result is that if the queue is stable, the move-along policy is optimal. 7 refs.

Li, Shuo-Yen Robert (Bell Communications Research, Morristown, NJ, USA). *IEEE Trans Autom Control* v 33 n 4 Apr 1988 p 386-389.

**085685 MULTISERVER QUEUE WITH NARROW- AND WIDE-BAND CUSTOMERS AND WIDE-BAND RESTRICTED ACCESS.** A multiserver queueing system with two classes of customers is considered: a type-1 (narrowband, NB) customer requires a single server, while each type-2 (wideband, WB) customer requests  $n$  of the  $m$  servers ( $n$  is not random). Servers allocated to a type-2 customer are seized and released simultaneously. Service times are exponentially distributed with mean  $1/\mu_i$  for type  $i$  customers ( $i = 1, 2$ ). Blocked type-1 customers are cleared while blocked type-2 customers may be delayed in an infinite waiting room. A type-1 customer enters service immediately upon arrival if at least one server is free, irrespective of the status of the type-2 queue. WB customers have restricted access to the service facility; a cutoff parameter specifies the maximum number of type-2 customers that can be in service at the same time. Two approaches, moment-generating functions and matrix-geometric techniques, are considered for the computation of the system performance, that is, the mean waiting time in queue and the probability of delay (i.e., nonzero waiting time) for type-2 customers, as well as the probability of blocking for type-1 customers. 34 refs.

**085686 RESEQUENCING DELAY FOR A QUEUEING SYSTEM WITH TWO HETEROGENEOUS SERVERS UNDER A THRESHOLD-TYPE SCHEDULING.** In service centers with multiple-parallel servers,

jobs may complete their service in a different order from the one in which they enter the center. In order to reestablish the original order resequencing protocols need to be implemented. It is shown that under a threshold-type policy, the resequencing delay depends on the strategy by which customers are selected and dispatched to the servers. Two selection strategies are developed, and the delay characteristics corresponding to the two strategies are studied. Existing methods for finding the sequencing delay are extended to cover the threshold-type policy. Closed-form solutions for the resequencing delay distributions under both selection policies are derived. To characterize the performance of the system under the two policies, two optimization criteria are introduced, namely, the fraction of customers that experience resequencing delay and the mean resequencing delay. These quantities are calculated explicitly, and their comparison reveals that the optimal decision is independent of the load on the system. The selection of the optimal policy under the first criterion depends only on the service rates, whereas for the second criterion the optimal selection depends on the threshold value and the ratio of the service rates. 10 refs.

**085687 TRANSIENT M/M/1 QUEUE VARIANCE COMPUTATION USING GENERALIZED Q FUNCTIONS.** A generalized  $Q$  function representation for the transient M/M/1 queue variance is developed. The expression is highly accurate and computationally efficient, and an upper bound on the error is easily calculated. For a  $Q$  function relative error of  $2 \times 10^{-12}$  using Parl's method, the relative error of the variance is generally less than  $10^{-9}$ . Average execution time is on the order of 70 ms per point on a VAX 11/750, but faster execution times can be obtained by using larger  $Q$  function relative errors. 13 refs.

**085688 APPROXIMATE ANALYSIS OF FORK-/JOIN SYNCHRONIZATION IN PARALLEL QUEUES.** An approximation technique, called scaling approximation, is introduced and applied to the analysis of homogeneous fork/join queueing systems consisting of  $K \geq 2$  servers. The development of the scaling approximation technique is guided by both experimental and theoretical considerations. The approximation is based on the observation that there exist upper and lower bounds on the mean response time that grow at the same rate as a function of  $K$ . Simple, closed-form approximate expressions for the mean response time are derived and compared to simulation results. The relative error in the approximation is less than 5% for  $K \leq 32$ . 8 refs.

**085689 ON A NUMERICAL METHOD FOR CALCULATING STATE PROBABILITIES FOR QUEUEING SYSTEMS WITH MORE THAN ONE WAITING LINE.** M.S. Keane et al. have proposed a new numerical method for calculating state probabilities for queueing systems with more than one waiting line in parallel. The method is based on power series expansions of state probabilities as functions of the traffic intensity of a system. The coefficients of these power series can be recursively calculated. The coefficients of the power series expansions of moments of queue length distributions can be derived from those of the state probabilities in a straightforward manner. The above method is discussed for a rather general class of exponential queueing systems. The asymptotic behavior of moments in heavy traffic is used to obtain extrapolations of the coefficients of their

power series expansions at the origin. The calculation of moments is strongly improved by means of these extrapolations. (Author abstract) 7 refs.

**085690 APPROXIMATE DISAGGREGATION AND PERFORMANCE BOUNDS FOR QUEUEING NETWORKS WITH MULTIPLE-SERVER STATIONS.** We introduce the concept of approximate disaggregation which enables us to replace a station by a subnetwork, i.e. a set of stations, such that the performance of the derived network is close to the performance of the initial network. We use this concept to disaggregate any multiple-server station into a set single-server stations. Using two different disaggregations, we are able to bound the performance of the initial network by the performance of a 'lower' and an 'upper' network each consisting of single-server stations, whose performance can in turn be bounded by the Balanced Job Bounds (or other known bounds). Several examples show the useful information provided by these bounds at a very low cost: for K stations and N customers, the computational complexity here is  $O(K)$  which is significantly less than the  $O(KN^2)$  operations required for exact solution. Indeed, despite the multiple server stations, the computational complexity of our bounds is the same as that of Balanced Job Bounds. (Author abstract) 24 refs.

**085691 ANALYSIS OF A CONVEYOR QUEUE IN A FLEXIBLE MANUFACTURING SYSTEM.** In a flexible manufacturing system stations are arranged along a common conveyor that brings items for processing to the stations and also carries away the processed items. At each station specialized robots automatically load and unload items on and off the conveyor. We examine here a single station in such a system. A new kind of queueing problem arises, with input-output dependencies that result because the same conveyor transports items both to and from the station. The paper analyzes two models of a station. Model 1 has one robot that cannot return a processed item to the conveyor while unloading a new item for processing. Model 2 has two robots to allow simultaneous loading and unloading of the conveyor. A principal goal of the analysis is the proper choice of the distance separating the two points at which items leave and rejoin the conveyor. (Author abstract) 5 refs.

**085692 MAXIMUM ENTROPY QUEUE LENGTH DISTRIBUTION FOR A G/G/1 FINITE CAPACITY QUEUE.** A new 'hybrid' analytic framework, based on the principle of maximum entropy, is used to approximate the queue length distribution of a G/G/1 finite buffer queue. Robust recursive relations are derived and asymptotic connections to the infinite capacity queue are established. Furthermore, 'equivalence' principles are applied to analyse two-stage cyclic queues with general service times and favourable comparisons with global balance solutions are made. Numerical examples provide useful information on how critically system behaviour is affected by the distributional form of interarrival and service patterns. It is shown that the maximum entropy solution predicts the bottleneck 'anomaly' and also it defines bounds on system performance. Comments on the implication of the work to the analysis and aggregation of computer systems are included. (Author abstract) 28 refs.

## Random Number Generation

**085693 VARIATE GENERATION FOR ACCELERATED LIFE AND PROPORTIONAL HAZARDS MODELS.** In reliability, covariates such as the turning speed of a machine tool or the stress applied to a component affect the lifetime of an item. Two models are often used to incorporate the effect of these covariates on lifetimes: accelerated life and proportional hazards models. We use accelerated life and proportional hazards lifetime models to account for the effects of covariates on a random lifetime. We find that variate generation algorithms for Monte Carlo simulation in both the renewal and nonhomogeneous Poisson process cases are a simple extension of the inverse cumulative distribution function (cdf) technique. (Edited author abstract) 8 refs.

**085696 ON THE PROBABILITY DENSITIES OF AN ORNSTEIN-UHLENBECK PROCESS WITH A REFLECTING BOUNDARY.** We show that the transition p.d.f. of the Ornstein-Uhlenbeck process with a reflection condition at an assigned state S is related by integral-type equations to the free transition p.d.f., to the transition p.d.f. in the presence of an absorption condition at S, to the first-passage-time p. d.f. to S and to the probability current. Such equations, which are also useful for computational purposes, yield as an immediate consequence all known closed-form results for Wiener and Ornstein-Uhlenbeck processes. The results are relevant to one-dimensional diffusion processes (Edited author abstract) 21 refs.

**085698 FIRST PASSAGE TIME INTERVALS OF GAUSSIAN PROCESSES.** The first passage time problem of a stationary Gaussian process is theoretically and experimentally studied. Renewal functions are derived for a time-dependent boundary and numerically calculated for a Gaussian process having a seventh-order Butterworth spectrum. The results show a multiplex property not only for the constant boundary but also for a linearly increasing boundary. The first passage time distribution densities were experimentally determined for a constant boundary. The renewal functions were shown to be a fairly good approximation to the distribution density over a limited range. (Author abstract) 8 refs.

**085699 ON USING DETERMINISTIC FUNCTIONS TO REDUCE RANDOMNESS IN PROBABILISTIC ALGORITHMS.** We show the existence of nonuniform schemes for the following sampling problem: Given a sample space with  $n$  points, an unknown set of size  $n/2$ , and  $s$  random points, it is possible to generate deterministically from them  $s + k$  points such that the probability of not hitting the unknown set is exponentially smaller in  $k$  than  $2^{-s}$ . Tight bounds are given for the quality of such schemes. Explicit, uniform versions of these schemes could be used for efficiently reducing the error probability of randomized algorithms. A survey of known constructions is included. (Edited author abstract) 17 refs.

**085700 SOME PROPERTIES OF SIMULATION INTERVAL ESTIMATORS UNDER DEPENDENCE INDUCTION.** Variance reduction techniques (VRTs) represent a choice between a crude experiment and a more statistically efficient experiment for estimating the parameters of a stochastic process. The most widely used VRTs change the joint distribution of the simulation output random variables upon which the point estimators are based. When this change is achieved by inducing dependence among input random variables we call them dependence induction (DI) VRTs. Some basic, but surprising properties of confidence intervals formed under antithetic-variables and common-random-numbers (VRT) are derived. It is shown that improved point estimator performance, the primary goal of variance reduction techniques, does not necessarily imply improved interval estimator performance. 18 refs.

**085701 PROBABILISTIC ANALYSIS OF THE NEXT FIT DECREASING ALGORITHM FOR BIN-PACKING.** Given a list of  $n$  items, the bin-packing problem is to find the smallest number of bins in which these items can be packed, subject to the constraint that the total size of the items packed in any bin cannot exceed 1. This problem is NP-hard, so researchers have turned to the analysis of simple heuristics. We are concerned with the Next Fit Decreasing (NFD) method. We use a simple deterministic inequality to simplify and strengthen previous results on the probabilistic analysis of Next Fit Decreasing for Bin-Packing. 4 refs.

**085702 ESTIMATION OF THE MEAN FROM RANDOMLY CENSORED DATA.** Let random variables  $Y_1, \dots, Y_N$  be i.i.d. according to continuous distribution function  $F$ , with finite mean  $\mu$ . Their measurements are censored from the right by the realizations of random variables  $V_1, \dots, V_N$ , independent mutually and of  $Y_i$ 's, too. We construct the estimator  $\mu_N = \sum T_i \cdot \Delta F_N(T_i) \cdot I_i / T_i$ , where  $T_i = \min(Y_i, V_i)$ ,  $F_N$  is the product limit estimator of  $F$ ,  $A_N \rightarrow \infty$  is a real sequence, conveniently chosen. The conditions are derived for strong consistency of  $\mu_N$  as well as for its asymptotic normality, and the rate of convergence is studied. Trimmed mean estimator is considered, too. (Author abstract) 5 refs.

**085703 ONE PROPERTY OF A SAMPLE AUTOCOVARIANCE OF PURELY RANDOM SEQUENCES AND ITS APPLICATION.** One odd property of the purely random sequences introduced: In the sample autocovariance of the purely random sequence the squared magnitude at the origin tends to the sum of the squared magnitudes except at the origin irrespective of the type of its probability distribution function. Further expressing the above property in the frequency domain we give the different approach to prove the known fact that the power spectrum of the purely random sequence is always different from its periodogram even if the number

of sample points tend to infinity. Finally, as an application we show that the noise periodogram can be estimated from the image degraded by the additive noise. (Author abstract) 17 refs.

**085704 OPTIMAL SEARCH FOR ONE OF MANY OBJECTS HIDDEN IN TWO BOXES.** A discrete search model for one of many objects hidden in two boxes is studied. The number of objects is assumed to be a random variable with a known prior distribution. When the box is searched, a cost is paid and the conditional probability of finding a specific object given it was hidden there is given. We are interested in determining a search which finds at least one object with minimum expected cost. Zones of the state space for which Blackwell's rule is optimal are characterized. Based on these results an algorithm for constructing an optimal search sequence is suggested and demonstrated in the case where the number of hidden objects has a geometric distribution. (Edited author abstract) 14 refs.

**085712 NUMERICAL TRANSIENT ANALYSIS OF MARKOV MODELS.** We consider the numerical evaluation of Markov model transient behavior. Our research is motivated primarily by computer system dependability modeling. Other application areas include finite-capacity queueing models, closed queueing networks, and inventory models. We focus our attention on the general problem of finding the state probability vector of a large, continuous-time, discrete-state Markov chain. Two computational approaches are examined in detail: uniformization and numerical linear multistep methods for ordinary differential equation solution. In general, uniformization provides greater accuracy but deals poorly with stiffness. A special stable ordinary differential equation solver deals well with stiffness, but it provides increased accuracy only at much greater cost. Examples are presented to illustrate the behavior of the techniques discussed as a function of model size, model stiffness, increased accuracy requirements, and mission time. (Author abstract) 26 refs.

**085713 EMPIRICAL STATIONARY DISTRIBUTION FUNCTION OF MARKOVIAN CORRELATED RANDOM SEQUENCES.** Considering a homogeneous recurrent  $(k+1)$ -node Markov chain with stationary d.f.  $F(x)$  it is shown that a so-called 'F(x)-equivalent' 2-node Markov chain can be associated to any point  $x$  and that thereupon the Bayes-Laplace-statistics for 2-node chains can be used to evaluate the correlated  $x$ -sequence generated by the  $(k+1)$ -node chain

yielding under large sample conditions simple posterior statements about its empirical stationary  $d_f F_n(x)$ , the associated relative error  $d_f(x)$  and also about a mean correlation coefficient  $\rho^-(x)$ . This statistical procedure can be generally applied not only discrete but also to continuous stationary processes with unknown properties; this is demonstrated in case of the heavily correlated delay time of queueing system M/M1. (Author abstract) 18 refs.

**085719 CONTINUOUS AND DISCRETE SEARCH FOR ONE OF MANY OBJECTS.** By an easy observation we show that the basic result of Blackwell according to which the most inviting strategy is optimal in a discrete search for one object, is also true when the number of objects is random provided the search is made in continuous time. This result does not hold in the discrete search model even when only two boxes are present (contrary to a conjecture of Smith and Kimeldorf). For the case of two boxes, a convenient sufficient condition on the distribution of the number of objects is provided which ensures optimality of the most inviting strategy. As a result, this strategy is shown to be optimal for several important distributions. (Edited author abstract) 9 refs.

**085721 DETERMINATION OF THE CHARACTERISTICS OF A RANDOM PROCESS AT THE OUTPUT OF A DIVIDER.** The probability characteristics of a random process  $\eta(t)$ , the quotient resulting from division of Gaussian random processes  $\xi_1(t)$ ,  $\xi_2(t)$  that are stationary in the broad sense have been considered. We shall consider a method for determining the probability characteristics of  $\eta(t)$  under the requirement that  $\xi(t)$  arrive at one of the divider inputs through a delay line with delay time  $\tau_d$  not exceeding the correction time  $\tau_k$  and that  $P_1(\xi)$  be described by a Rayleigh law. The method considered makes it possible to determine the probability characteristics of a random process at the output of a divider for various forms of random processes input. 4 refs.

**085722 STATIONARY MARKOV RENEWAL PROCESS ON THE WHOLE TIME AXIS.** Markov renewal process (MRP) is widely used in communication theory, OR, physics and so on. This paper is concerned with the mathematically rigorous construction of the stationary MRP with finite states on the whole time axis. A joint (forward and backward) invariant probability exists uniquely for an irreducible MRP. A stationary MRP on the whole time axis is defined by setting the joint invariant probability at the point of origin and by forming the MRP in the positive direction and the reverse MRP in the negative direction. An elementary proof of the stationarity of the defined process is given by showing directly that any finite-dimensional distribution is invariant under the shift of time. The proof of the existence and uniqueness of the joint invariant probability is also presented. Once the stationarity of the defined MRP is established, various stochastic processes generated by it can be shown to be stationary as well. (Edited author abstract) 8 refs.

**085723 SYMMETRY PROPERTIES OF HIGH-ORDER SPECTRAL DENSITIES OF STATIONARY AND PERIODIC-NONSTATIONARY STOCHASTIC PROCESSES.** In this study, we consider the high-order spectral densities of a periodic-nonstationary stochastic process. The main focus is on the symmetry

properties of spectral densities of orders  $v=3, 6$ . In parallel we describe the symmetry properties of the high-order spectral densities of discrete- and continuous-time stationary stochastic processes. The symmetry properties of the high-order spectral densities obtained in this study reduce the computational work necessary for their estimation. 8 refs.

**085724 ADAPTIVE PREDICTION FOR ARMA PROCESSES WITH MARKOV SWITCHING PARAMETERS.** The problem of prediction for ARMA processes with switching parameters modelled as a finite-state Markov chain is considered. The Markov transition probability matrix is assumed to be unknown but constant and can take values only from a finite collection which contains the true transition matrix. A multiple-model prediction method is presented. The digital simulation shows a good performance of the proposed predictor. (Author abstract) 15 refs.

**085725 FILTERING ALGORITHM FOR ONE CLASS OF DISCRETE-CONTINUOUS MARKOV PROCESSES.** In utilization of filtering algorithms for discrete-continuous Markov processes (DCMP) there is a typical situation in which the parameters of the mixture received may be described by two vector Markov processes  $\beta$ ,  $\lambda$  with different minimum correlation time for the respective components. A DCMP filtering algorithm has been obtained by the author previously for constant  $\beta$ . Here the results are extended to the case of variable  $\beta$ , also including the parameters of the random delay in subelements of the signal. A new algorithm has been obtained that is optimal in Gauss approximation for DCMP filtering that generalizes the approximate algorithms obtained elsewhere that use feedback with respect to a discrete parameter (ADFPB) and with overassignment of continuous parameters (AOCP). 3 refs.

**085726 PREDICTION IN ZERO-ONE RANDOM SEQUENCES.** A method for prediction in sequences of random variables which assume only two values (say zero and one) is derived. The method is based on the application of the higher order Markovian model with pair interactions and it suits well in case of rather short sequence of observed data and long range of dependence. The obtained result is formulated in a way which is easy to be implemented and a numerical example with simulated data is included. (Author abstract) 5 refs.

**085727 IMPROVED ALGORITHM TO APPROXIMATE THE BEHAVIOR OF FLOW LINES.** An approximation method is given for the analysis of flow lines with a continuous product flow. The algorithm is an improvement of an earlier developed method. It is applied here to lines in which the machines are unreliable with exponentially distributed life and repair times. All intermediate buffers have finite capacity. The algorithm consists of repeated decomposition and aggregation steps, in which two-stage lines are approximated by a single machine. The method appears to be fast and performs well for lines which are not too long. (Edited author abstract) 14 refs.

**085728 NEW RESULTS ON THE ENUMERATION OF NON-INTERSECTING RANDOM WALKS.** Many attempts have been made to obtain approximations and closed forms for the generating function enumerating

non-intersecting (self-avoiding) walks on a periodic lattice. In this paper we introduce an approach based on the Mayer cluster theory of imperfect gases and liquids and apply it to a continuum model and to a lattice model. The combinatorics are appreciably simpler than it is to a continuum model and to a lattice model. The combinatorics are appreciably simpler than for the Mayer problem. We have not yet solved any such problems analytically, but a combination of analytical work and a series expansion enables us to approach the exact generating functions as closely as we please. The starting point is an approximation very similar to the Percus-Yevick approximation for liquids and this can be progressively improved upon. (Author abstract) 10 refs.

**085729 FIRST PASSAGE APPROXIMATION FOR NORMAL STATIONARY RANDOM PROCESSES.** A new approximate solution for the first passage probability of a stationary Gaussian random process is presented which is based on the estimation of the mean clump size. A simple expression for the mean clump size is derived in terms of the cumulative normal distribution function, which avoids the lengthy numerical integrations which are required by similar existing techniques. The method is applied to a linear oscillator and an ideal bandpass process and good agreement with published results is obtained. By making a slight modification to an existing analysis it is shown that a widely used empirical result for the asymptotic form of the first passage probability can be deduced theoretically. **085730 EFFICIENT SOLUTION PROCEDURE FOR TRANSIENT MARKOV PROCESSES.** We present a procedure for computing transient solutions to discrete state space, continuous time Markov processes. This procedure, based on the Laplace transform, computes transient state probabilities. The technique is applied to a Markov process model of a two-unit cold standby system for illustrative purposes. The main advantage of the procedure is that the time value has no effect on the time needed to compute the state probabilities. (Author abstract) 4 refs.

**085732 APPROXIMATION FOR OPTIMAL STOPPING OF A PIECEWISE-DETERMINISTIC PROCESS.** This paper deals with approximation techniques for the optimal stopping of a piecewise-deterministic Markov process (P.D.P.). Such processes consist of a mixture of deterministic motion and random jumps. We study the optimal stopping problem with lower semianalytic gain function; our main result is the construction of  $\epsilon$ -optimal stopping times. We consider a P.D.P. satisfying some smoothness conditions, and for  $N$  integer we construct a discretized P.D.P. which retains the main characteristics of the original process. By iterations of the single jump operator from  $R^N$  to  $R^N$ , each iteration consisting of  $N$  one-dimensional minimizations, we can calculate the payoff function of the discretized process. We demonstrate the convergence of the payoff functions, and for the case when the state space is compact we construct  $\epsilon$ -optimal stopping times for the original problem using the payoff function of the discretized problem. A numerical

example is presented. (Edited author abstract) 24 refs.

**085733 EMPTY ENVELOPE EXCURSIONS IN STATIONARY GAUSSIAN PROCESSES.** The probability of the adverse event of upcrossing, within a given time interval, of some critical level by some structural random vibration response quantity is usually evaluated on the conservative side in terms of the mean upcrossing rate. Due to clumping of the upcrossings the evaluation may become overly conservative. This is remedied by only counting the non-empty excursions above the level of a suitable envelope of the response. Some excursions can be 'empty' in the sense that no upcrossings of the response occur during the excursion of the envelope. The long run fraction of empty excursions of the Cramer-Leadbetter envelope is evaluated for a stationary and ergodic Gaussian process by use of the regression method. The formula obtained is an approximation that improves earlier assessments due to Vanmarcke. (Edited author abstract) 7 refs.

**085734 SIMPLE AND EFFICIENT ALGORITHM TO COMPUTE TAIL PROBABILITIES FROM TRANSFORMS.** We present an algorithm to approximately compute the 'tail' probability that a random variable exceeds a specified number, given only an expression for its transform. We also show that the problem is #P-hard (more difficult than NP-hard), suggesting that no efficient procedure can solve it exactly. Our method consists essentially of summing a power series, and thus is easy to perform and requires little memory. Furthermore, its computational effort is nearly linear in the reciprocal of a prescribed worst-case error bound. (Author abstract) 6 refs.

**085735 DISTRIBUTION OF THE VALUES OF A RECURSIVE PULSED PROCESS.** The fact is now firmly established that processes whose properties are very similar to those of random processes can arise in strictly deterministic dynamic systems without any 'contaminating' noise. Radio-electronic devices occupy a special place among systems capable of stochastic behavior. A deterministic process in the form of a sequence of uniformly spaced pulses with recursively related amplitudes is considered. The distribution function of the process is derived by time averaging, and its properties are studied. The conditions under which this distribution approaches a normal distribution are investigated. **085736 REDUCTION OF PERTURBED MARKOV GENERATORS: AN ALGORITHM EXPOSING THE ROLE OF TRANSIENT STATES.** A new algorithm for the hierarchical aggregation of singularity perturbed finite-state Markov process is derived. The approach taken bridges the gap between conceptually simple results for a relatively restricted class of processes and the significantly more complex results for the general case. The critical role played by (almost) transient states is exposed, resulting in a straightforward algorithm for the construction of a sequence of aggregate generators associated with various time scales. These generators together provide a uniform asymptotic approximation of the original probability transition function. (Author abstract) 21 refs.

**085741 MODEL ORDER ESTIMATION FOR PARTIALLY OBSERVED MARKOV CHAINS.** Model order estimation for the partially observed Markov chain (POMC), also called the hidden Markov model, is addressed. Model order is defined as the number of independent model parameters. Simulation is used to investigate the small sample performance of a number of model order criteria, as applied to POMC models with low state dimension and binary observations. Consistency of these criteria in the context of POMC models with discrete state and observation space is also investigated. A criterion due to Akaike is shown not to be consistent. Simulation results indicate that Akaike's criterion can provide more accurate estimation in the small sample case. (Author abstract) 18 Refs.

**085742 STOCHASTICALLY MINIMIZING TOTAL PENALTY COSTS IN THE TWO-MACHINE FLOW SHOP WITH RANDOM PROCESSING TIMES.** A set of  $n$  jobs is to be processed on two machines in series. The job processing times are independent random variables. We first develop a sufficient condition on the processing time distributions to reduce stochastically a total penalty cost function. We then establish, for exponential job processing times, a set of sufficient and transitive conditions for stochastically

minimizing a total penalty cost function. Two examples are given to illustrate the results. (Author abstract). 11 refs.

**085743 MULTIVARIATE STOCHASTIC DOMINANCE WITH FIXED DEPENDENCE STRUCTURE.** Stochastic dominance conditions for multivariate prospects are provided under the assumption of equal dependence structure for the prospects. These conditions are easily testable since they involve only the marginal distribution functions. This note proves that the crucial assumption is not independence, but rather the fact that the two random vectors have the same dependence structure, in a sense that will be specified. Therefore, whenever two random vectors have the same dependence structure, then multivariate stochastic dominance conditions may be provided simply by examining the marginal distribution functions of each of the components of the random vectors. **085744 IMAGING BLACK BOXES WITH MULTIPLE STOCHASTIC OUTPUT.** A black box is modeled by decomposition into an unknown but finite number of independent noise sources and of independent signal sources. Signal sources carry signals in strict relation to an input signal vector. Output signal vectors are transformable into a system-state vector by means of stochastic properties of an assembly of independent noise sources. By proper scaling such system-state vectors are measurable. The internal organization structure can be imaged by the correlation of components of the state vector. This correlation reflects overlap of so-called activity profiles which are defined by the fraction of signal sources and of noise sources used in the formation of a response. In accordance with the two kinds of sources, there are two complementary images, for overlap of noise sources and for overlap of signal sources, respectively. 6 refs.

**085745 ON THE DISTRIBUTION OF POSITIVE-DEFINITE GAUSSIAN QUADRATIC FORMS.** To describe the performance of quadratic signal processing used in detection and estimation of random signals, the probability distribution, of the output of the processor is needed. Positive-definite Gaussian quadratic forms are considered here. The quadratic form is diagonalized in terms of independent Gaussian variables and its mean, moment-generating function, and cumulants are computed. Conditions are given for the quadratic form to be  $\chi^2$  distributed and distributed like a sum of independent random variables having a Gamma distribution. A method is proposed to approximate its probability distribution using an expansion in Laguerre polynomials for the central case and in generalized  $\chi^2$  distributions in the noncentral case. The series coefficients and bounds on truncation error are evaluated. Some applications in average power and power spectrum estimation and in detection illustrate the method. 32 refs.

**085749 ESTIMATION IN A RANDOM CENSORING MODEL WITH INCOMPLETE INFORMATION: EXPONENTIAL LIFETIME DISTRIBUTION.** Analysis of methods and simulation results for estimating the exponential mean lifetime in a random-censoring model with incomplete information are presented. The instant of an item's failure is observed if it occurs before a randomly chosen inspection time and the failure is signaled. Otherwise, the experiment is terminated at the instant of inspection during which the true state of the item is discovered. The maximum-likelihood method (MLM) is used to obtain point and interval estimates for item mean lifetime, for the exponential model. It is demonstrated, using Monte Carlo simulation, that the MLM provides positively biased estimates for the mean lifetime and that the large-sample approximation to the log-likelihood ratio produces accurate confidence intervals. The quality of the estimates is slightly influenced by the value of the probability of failure to signal. Properties of the Fisher information in the censored sample are investigated theoretically and numerically. 5 refs.

**085753 PROBABILITY DENSITIES FOR CONDITIONAL STATISTICS IN THE CUBIC SENSOR PROBLEM.** This paper applies the techniques of Malliavin's stochastic calculus of variations to Zakai's equation for the one-dimensional cubic sensor problem in order to study the existence of densities of conditional statistics. Let  $\{X_t\}$  be a Brownian motion observed by a cubic sensor corrupted by white noise, and let  $\phi$  denote the unnormalized conditional estimate of  $\phi(X_t)$ . If  $\phi_1, \dots, \phi_n$  are linearly independent, and if  $\Phi = (\phi_1, \dots, \phi_n)$ , it is shown that the probability distribution of  $\Phi$  admits a density with respect to Lebesgue measure for any  $n$ . This implies that, at any fixed time, the unnormalized conditional density cannot be characterized by a finite set of sufficient statistics. (Author abstract) 13 refs.

**085755 RESPONSE OF PLANAR POTENTIOMETRIC PROBES TO CHANGES IN POLARIZATION CONDITIONS OF THE COPPER ELECTRODE.** The concentrations of species having an intermediate oxidation state (SIOS) generally are measured with indicator electrodes. It is the aim of this work to describe a potentiometric indicator electrode which can be used for measuring the concentration changes of SIOS under transient conditions. It is found that the concentration changes which occur in the solution layer next to the electrode when a cathodic current is turned on in a  $\text{Cu}^{2+}$

-ion-containing solution consist of an accumulation and consumption of Cu+ SIOS. The data reported also show that planar indicator electrodes can be useful in solving electrochemical problems, since universal information can be obtained; they can be used when studying the transient changes in the concentrations of SIOS at electrodes in real hydrodynamic situations. The concentration changes in the layer next to the electrode can be estimated from the current of SIOS oxidation when planar platinum indicator electrodes are used. 14 refs.

**085756 INVESTIGATION OF BUBBLE DYNAMICS IN POOL BOILING IN HIGH HEAT FLUX REGION.** It has been hypothesized that the pool boiling at high heat flux is characterized by the formation of a liquid layer known as macrolayer which is trapped between the heating surface and the vapor mass. The thickness of the macrolayer and the initiation, growth and departure cycle periods of the vapor mass have been found to be the critical parameters that determine heat flow rate from heated surface. The theory of electric probe method to determine bubble emission frequency and initial thickness of the liquid macrolayer has been described in this paper. The experimental procedure has been found to give results which conform to the findings of previous investigators. This simple though indirect method could be used for detailed investigations of bubble dynamics at high heat fluxes. (Author abstract) 8 refs.

**085757 TECHNIQUE FOR MEASUREMENT OF JET PENETRATION IN HOT FLUIDIZED BEDS WITH A MODIFIED PITOT-TUBE PROBE.** A miniature probe with a modified Pitot-tube design was developed to measure the local momentum flux in a fluidized bed. With this probe, and with an isolated jet in the grid zone of a high-temperature fluidized bed, an experimental technique to locate a jet and measure the jet penetration was developed. At the measured jet height, dynamically, the jet phase becomes homogeneous with the surrounding emulsion phase; visually, this corresponds to the height where the bubble detaches from the jet. With this technique, invisible jets at the interior of the bed can be located and their penetration heights measured. A semiempirical procedure is suggested to measure the width of the dynamic core of the jet with this probe. (Edited author abstract) 15 refs.

**085760 PARTICLE VELOCITY MEASUREMENTS THROUGH ELECTROSTATIC FIELD FLUCTUATIONS USING EXTERNAL PROBES.** Two probes for measuring particle velocity and flowrate based on the electrostatic field nature of a pneumatic transport system are introduced. The first probe is based on the current of charged particles inducing a current in a coil placed perpendicular to the flow. The magnitude of the current induced appears to be related to the amount of charged particles passing through the coil and the velocity of the particles. The second probe utilizes fluctuations in the electrostatic field which are picked up by two probes placed a fixed distance along the axis of the flow. The signals from these two probes are identical in waveform but offset in time, therefore, particle velocity can be obtained by cross-correlation techniques. (Edited author abstract) 6 refs.

## Calibration

**085761 FREQUENCY RESPONSE OF A CONSTANT-TEMPERATURE HOT-WIRE TO TEMPERATURE FLUCTUATIONS.** A temperature-sensitive hot-wire under constant-temperature operation is analyzed to predict its frequency response to temperature fluctuations of the fluid. Effects of the finite Wollaston length, the over-heat ratio and the transconductance of the amplifier are taken into account, and a precise expression for the transfer function is derived. Various probes with different geometries are dynamically calibrated using the new developed procedure, in which a linear temperature distribution or a thermal wake just behind parallel line-sources is utilized to generate prescribed temperature fluctuations over a wider range of frequencies. Good agreement is obtained between the predictions and the experimental results on the gain of the sensitivity. (Edited author abstract) In Japanese. 4 refs.

**085762 RIG FOR THE STATIC CALIBRATION OF CONSTANT-TEMPERATURE HOT WIRES AT VERY LOW VELOCITIES.** A rig for the calibration of hot-wire anemometer probes at velocities below 1 m/s that uses a stepping motor to drive the probe at controlled velocities down the center of an enclosed channel is described. A typical calibration curve (over the range 0.02-1 m/s) displays the usual characteristics of a hotwire probe under combined natural and forced convection. A reasonable degree of fit with an equation of the form proposed by Van der Hegge Zijnen is demonstrated. Repeated calibrations confirm the very high accuracy of the rig, which demonstrates its suitability for detailed study of this interesting flow regime as well as for straightforward calibration. (Author abstract) 6 refs.

## Components

**085763 SPIN POLARIZATION ANALYZER ATTACHMENT TO A SCANNING AUGER MICRO-PROBE.** A new, compact electron spin polarization

analyzer attachment to a scanning Auger microprobe has been described. Its operation and present performance have been demonstrated using the SEMPA technique to image the surface magnetic microstructure of three different types of magnetic samples. The unique advantages of SEMPA have been identified previously; those that were illustrated in these applications are: (1) the technique is surface sensitive; (2) the magnetic structure is imaged independently of the surface topography; (3) the contrast and signal are large; and (4) all three components of the polarization can be determined and therefore the surface magnetic vector can be mapped. Additionally, high spatial resolution can be achieved. (Author abstract). 11 refs.

**085764 DIRECT COUPLING OF OPEN-TUBULAR LIQUID CHROMATOGRAPHY WITH MASS SPECTROMETRY.** The design and performance of a probe that allows direct liquid introduction of the total effluent of an open-tubular liquid chromatography (OTLC) column into a mass spectrometer are described. No modification of the mass spectrometer source is required, and the probe is introduced through the direct insertion probe inlet. Because flow rates are less than 0.1  $\mu\text{L}/\text{min}$ , this system can be used under both conventional electron impact and chemical ionization mass spectrometric conditions. (Edited author abstract) 20 refs.

**085765 DESIGN AND CALIBRATION OF A GAMMA RAY TRANSMISSION DENSITY PROBE.** A dual probe gamma ray transmission gage has been designed in LNETI for the measurement of soil porosities and bulk densities. The gage makes use of a 4 cm GM counter and of a  $^{137}\text{Cs}$  source, and can be operated at a source-detector distance of either 20 or 30 cm. The gage performance and main parameters were studied experimentally as well as by means of a computer simulation. The experiments were carried out both in the laboratory and on the field. Monte Carlo simulations were performed for both Cs and Co sources and the two source-detector distances. Reported here are calibration curves for sensitivity, relative statistical errors and resolution. Good agreement has been found between simulated and experimental data. (Author abstract) 4 refs.

## Fabrication

**085766 FABRICATION AND CHARACTERIZATION OF A FIBER-OPTIC-BASED SPECTROELECTROCHEMICAL PROBE.** Probes were constructed from fused silica optical fibers embedded in electrically conductive graphite/epoxy material with the optical end face and the working electrode active surface in a coplanar arrangement. The electrochemical properties and spectroelectrochemical response of the microprobe were characterized in solutions and in gels containing UV-absorbing oxidizable compounds. The concept of electrochemical modulation of spectral signals for fiber-optic-assisted spectroscopy was demonstrated by using the ascorbate/dopamine gel model. (Edited author abstract). 15 refs.

**085767 FABRICATION OF AN INTEGRATED MICROPROBING HEAD FOR FAULT ANALYSIS OF MOS INTEGRATED CIRCUITS.** The fabrication of an integrated microprobing head for fault analysis of MOS ICs is described. The microprobe is etched out from a silicon wafer to a tip size of about 10  $\mu\text{m}$  and it has an NMOS impedance transformer integrated very close to the tip. The input capacitance of this device is smaller than 0.1 pF and the delay time (at 50% of the final value) is lower than 100 ns at a 100 k $\Omega$  signal source resistance. This is a significant improvement on the response time of a conventional microprobe. (Author abstract) 4 refs.

**Optimization** See Also ELECTRON BEAMS.

**085769 OPTIMIZATION OF SMALL ELECTRON PROBES.** The size of an electron probe is determined by many different factors including diffraction, lens aberrations, space charge and defocus. In many applications it is desirable to optimize the probe to achieve the smallest size (or, equivalently, the best resolution). This is particularly difficult to do when the effect of diffraction is significant. We have noted that many of the published approaches to this problem are based upon false premises and give erroneous results. In this paper we attempt to correct at least some of these errors, although it is undoubtedly true that some remain. (Author abstract) 8 refs.

**Performance**

**085770 PERFORMANCE OF A LOW-VOLTAGE HIGH-CURRENT-DENSITY ELECTRON PROBE.** A low-voltage high-current-density electron probe has been constructed. Electrons are extracted at 7 kV from a zirconiated tungsten thermal field emission source, pass through a two-lens collimated optical system, and are decelerated by a retarding field at the sample. A focused probe is obtained at 1-keV landing energy with 40-nm diameter and 320-nA current. The corresponding peak current density is  $1.3 \times 10^4 \text{ A/cm}^2$ . This result shows that space-charge beam broadening is much better controlled in these retarding field probes than in conventional low-voltage column designs where the extraction and landing energies are equal. 17 refs.

**085773 ADAPTIVE OPTIMAL CONTROL OF DYNAMIC DISTRIBUTED OBJECTS.** The design of mathematical software for automatic technological process control systems requires the development of simple and effective control algorithms with feedback. The control problem becomes more complex if the parameters

of the model of the object are unknown and must be corrected in the course of operation of the closed system. Control algorithms can be significantly simplified using nonterminal (local) optimality criteria and sufficiently effective adaptive identification algorithm. The method of synthesis of adaptive control algorithms with identification, developed for lumped systems, is extended here to certain classes of distributed dynamic systems. 12 refs.

**085778 PROCESS CAPABILITY: ONE ELEMENT OF ZERO INVENTORIES.** The process capability study addresses whether the process is in control and whether the process is stable. It should be noted that the application of process capability analysis does not yield benefits in zero inventories environments alone; any manufacturing environment can gain significant improvement through its application. Further, this technology has an indirect impact on planning and scheduling; after all, if process yield can be predicted and controlled, disruption from manufacturing fallout will be lessened, and schedules can be more effectively stabilized. The application of this theory requires in-depth understanding and working

knowledge of the principles and techniques of statistical inference and prediction and their application to data samples and quality assurance. 7 refs.

**085781 STATISTICAL PROCESS CONTROL... THE OTHER SIDE OF THE QUALITY COIN.** Traditional quality control techniques are being challenged today by statistical process control (SPC) - a quality control alternative that reduces piece-part variability, concentrates process variables around a target, increases productivity, and ultimately results in more economic production. Developed in this country more than 50 years ago, its value has only recently been recognized in the U.S. This article explains what SPC is, details the benefits it provides, and discusses how it is best applied. The article concludes with a look at how SPC was successfully applied at Kavlico in the production of capacitive thick film pressure transducers.

Constantinou, Tat A. (Kavlico Corp, Moorpark, CA, USA). *Chilton's I&CS* v 60 n 11 Nov 1987 p 45-47.

**085782 PRODUCTION CONTROL ON THE BASIS OF FUZZY MODELS.** The efficiency of modern control systems for controlling production - of integrated automatic systems for continuous processes and flexible systems for discrete processes - is largely determined by the quality of models and algorithms for solving functional tasks corresponding to the level of control hierarchy. Experience shows that in control systems uncertainty of qualitative character is easily taken into consideration by applying the body of mathematics of fuzzy set theory. (Edited author abstract) 11 refs.

**085784 TECHNIQUES FOR DISPLAYING MULTIVARIATE DATA.** A major concern in the process industry is how to convey the myriad of process parameters to an operator in a way that is easily apprehended. The purpose of this paper is to present some of the graphical techniques that may allow effective presentation of this multivariate data. The techniques presented are integrated displays and include gray-scale tables, linear profiles, star charts, n-fold circular displays, and faces. (Author abstract) 4 refs.

Simcox, William (Consulting Statisticians Inc). *Process Technol: A Compil of Rec Eng Conf Pap on Process Control and Simul* Publ by TAPPI Press, Atlanta, GA, USA, 1985 p 155-159.

**085785 STATE OF CHEMICAL PROCESS CONTROL: AN INDUSTRIALIST'S VIEW.** The author traces advances in process control over the last 25 years and assesses the current state of the technology. Areas for future development are outlined. The author argues that while chemical process control has made very significant advances in the last 25 years it has really only scratched the surface of its potential. By ensuring that the processes meet the target there are enormous benefits to be achieved in reducing capital and revenue costs.

Benson, R.S. (ICI plc, Billingham, Engl). *Chem Eng Res Des* v 65 n 6 Nov 1987 p 451-452.

**085786 ROBUST PROCESS CONTROL.** Model uncertainty is one of the major problems facing control system designers in practice. In this paper a general approach is outlined for the assessment of the effects of model uncertainty on control system performance. Also discussed are methods for the design of controllers which meet given performance specifications despite model uncertainty. The power of the new techniques as well as the failure of the traditional ones is illustrated on two examples widely studied in the process control literature: The design of Smith predictor controllers and the design of 2-point composition controllers for high purity distillation columns. (Author abstract) 42 refs.

Morari, M. (California Inst of Technology, Pasadena, CA, USA). *Chem Eng Res Des* v 65 n 6 Nov 1987 p 462-479.

**085787 ADAPTIVE PROCESS CONTROL.** This paper reviews some recent developments in the area of adaptive control. It is pointed out that global stability in the root mean square sense is not necessarily indicative of good steady state and transient performance. This problem is in part due to slow parameter drift and the lack of process excitation. The inclusion of leakage and/or a deadzone function can help solving this particular problem. A linear programming formulation of the finite receding horizon control problem allows for the inclusion of process constraints. (Author abstract) 58 refs.

Ydstie, B.E. (Univ of Massachusetts at Amherst, Amherst, MA, USA). *Chem Eng Res Des* v 65 n 6 Nov 1987 p 480-489.

**085788 CONTROLLING PROCESSES WITH INVERSE RESPONSE AND DEAD TIME.** Model based control such as a Smith Predictor or a dynamic reconciliator has been applied successfully in control of systems with a major dead time. Some processes, however, show an inverse response and major dead time as well. This paper proposes a technique for the compensation of both these effects. The technique has been successfully applied to temperature difference control of a chemical reactor. 5 refs.

**085789 TOTAL MANUFACTURING PROCESS CONTROL - THE HIGH ROAD TO PRODUCT CONTROL.** Total manufacturing process control in-

volves: getting a clear definition of what is required of the product; understanding the production process; improving the process so that an acceptable product is manufactured; controlling and monitoring the process itself; searching out new quality improvement opportunities. Different tools must be used, depending on the activity's complexity and whether one is dealing with variables, attributes, or some combination thereof. These steps are applicable to any manufacturing operation, and if properly followed, will lead to the required quality level in an expeditious and cost-effective manner. The steps should be continuously repeated to bring about better and better quality at lower and lower cost. 11 refs.

Tunmer, Joseph R. *Qual Prog* v 20 n 10 Oct 1987 p 43-50.

**085790 COMMON-SENSE APPROACH TO SPC.** A common sense platform is offered to combat the confusion concerning the statistical process control widespread in the USA. It is argued that: production employees need only a working knowledge of SPC; one should generate only the quantity of data that one's organization can digest; one should concentrate on the areas with the greatest cost effect first; one should realize that statistics is a tool; that statistics is not corrective action; one should work for continuous improvement. 1 ref.

Leppelmeier, John W. *Qual Prog* v 20 n 10 Oct 1987 p 62-64.

**085791 STATISTICS FOR THE SMALL-LOT JOB SHOP.** Statistical process control (SPC) has not been easy for many companies in the United States because it is thought that the technique is only applicable to high volume shops. This article describes methods which are suitable for small volume shops. The methods are gage repeatability and reproducibility, part family, minicapability and process evaluation studies.

Dovich, Robert A. (American Technologies Inc, Marshall, MI, USA). *Mach Tool Blue Book* v 83 n 1 Jan 1988 p 10, 12.

**085792 WHAT IS STATISTICAL PROCESS CONTROL?** The SPC approach to quality assurance can be defined as prevention of errors and producing products that come off the production line perfect the first time and every time. SPC is also a form of stressing quality throughout the entire company including sales and administrative personnel. With SPC each position within the company has a documented list of requirements to be fulfilled by the person holding the position. In addition, there are precise measurements to evaluate how well the requirements are carried out. Each employee must be aware of how his or her contribution affects the quality of the final product. Statistical process control is meant to control just the normal variations of a manufacturing process. There are several types of monitoring systems used in statistical process control. Control charts give a very complete picture of the quality of a product with a minimum amount of testing.

Anon. *Fastener Age* v 2 n 1 Jan-Feb 1988 p 23-24.

**085793 ROBUST POLE-PLACEMENT SELF-TUNING CONTROLLER FOR CHEMICAL PROCESS CONTROL: THEORETICAL STUDIES AND SIMULATION.** A single variable pole-placement self-tuning controller (PPSTC) is used to simulate examples typical of chemical processes; i.e., open-loop stable, unstable, and unstable non-minimum phase systems with unknown varying process dead time. The PPSTC is shown to be effective in each case. Set-point tracking and rejection of randomly occurring deterministic disturbances for all three types of processes are achieved. Simultaneous estimation of process parameters and process time delay is realized by using a recursive extended least squares method. (Author abstract) 13 refs.

Rohani, Sohrab (Univ of Saskatchewan, Saskatoon, Sask, Can); Quail, Douglas W. *Chem Eng Technol* v 11 n 1 Feb 1988 p 57-62.

**085794 USING STATISTICAL PROCESS CONTROL WITH ROBOTIC TESTING IMPROVES QUALITY LEVEL.** The proper application of statistical process control (SPC) in conjunction with 100% robotic testing can yield a very high reduction in parts per million defect (PPM) levels. SPC can eliminate the variability and identify process problems, while 100% robotic testing can detect and extract defective components caused by chance occurrences. The article presents a case study wherein a company utilizes the bakayoke (the Japanese term for devices that automatically check for abnormalities in a process). The bakayoke was to sort out defective product, and if an increased amount of product was rejected, would effectively flag when the process may be working incorrectly. The result was a substantial reduction in PPM defect levels and a corresponding cost savings.

BenDaniel, Elisabeth (Haemonetics). *Ind Eng (Norcross GA)* v 20 n 2 Feb 1988 p 26-29, 31.

**085795 ATTENDING TO ANCILLARIES.** The highly interactive nature of modern processes means that it is becoming increasingly necessary to specify in terms of 'criticality' a whole range of ancillary systems. Any failure in these systems may result in a costly and possibly dangerous breakdown of the entire process. One important ancillary which increasingly displays this criticality to the ultimate degree is heating, ventilating and air-conditioning (HeVAC) plant. As an example, the article briefly discusses the design of the HeVAC systems at Heysham power station.

Hodgson, Trevor. *Process Eng (London)* v 68 n 9 Sep 1987 p 55-57.

**085796 SPC: A MANAGEMENT TOOL TOWARDS PRODUCTIVITY IMPROVEMENTS.** Statistical Process Control is becoming more important than ever in the industries for better quality and high productivity. The author wants to emphasize the importance of SPC as an important tool, giving new dimensions to the industries. Various steps involved in implementing the program are also discussed with a detailed process analysis flow chart. SPC success depends on the support at all levels. The implementation of the program is not an overnight process and once the problem is solved, continuous monitoring of the process is necessary. Different steps of continual quality improvement are also discussed in the article. (Author abstract) 3 refs.

Singh, Durgesh K. (Klinger Electric Corp, Jackson, MS, USA). *Adv Manuf Processes* v 2 n 3-4 1987 p 259-266.

**085797 ADAPTIVE INFERENCE CONTROL FOR CHEMICAL PROCESSES WITH PERFECT MEASUREMENTS.** A single-input/single-output (SISO) adaptive inferential control system is proposed to deal effectively with real process control problems characterized by unmeasured disturbances, nonlinearities, and/or time-varying process parameters. The basic structure of an inferential (internal model) control system is coupled with an on-line parameter estimation method for estimation of the process model parameters and adjustment of the controller. To obtain a stable approximation to the inverse of the process model for use as the controller, the use of adaptive inverse modeling based on discrete convolution model is examined. (Edited author abstract) 18 refs.

Shen, Gwo-Chyau (Ohio State Univ, Columbus, OH, USA); Lee, Won-Kyoo. *Ind Eng Chem Res* v 27 n 1 Jan 1988 p 71-81.

**085798 MEASUREMENT EFFICIENCY IN A CONTROL SYSTEM.** The author considers the construction of a local sensor criterion consistent with the efficiency criterion of the entire control system. This criterion is applied to select a sensor for an optimal stabilization system of a stochastic delayed plant. It is shown that when constructing a consistent local criterion of the sensor, it is necessary and sufficient to identify its kernel with the global criterion kernel and to select its hull allowing for the properties of the global criterion hull and the desired properties of the local criterion. Two methods

have been proposed in order to isolate the global criterion kernel: the method of successive stripping of hulls and the method of reconstructing the kernel from its partial derivatives. For the mean-square optimal stabilization system of a stochastic delayed plant, we have obtained a consistent local sensor criterion having the properties of uncertainty function, which is more convenient in analysis and application than the global criterion. (Edited author abstract) 15 refs.

**085800 IMPROVED MULTILoop SINGLE-INPUT/SINGLE-OUTPUT (SISO) CONTROLLERS FOR MULTIVARIABLE PROCESSES.** Three methods are proposed for improving the performance of multiloop single-input/single-output (SISO) controllers which have been tuned by an approach illustrated in an earlier paper. In that paper, multiloop PI controllers were designed by detuning the controllers equally from SISO Ziegler-Nichols settings until a multivariable stability criterion was satisfied. In the present paper, several methods are described for adding derivative action to the PI controllers. An empirical procedure is developed for weighting the detuning of the loops by the predicted final ITE of the process after load and set-point disturbances. (Edited author abstract) 10 refs.

**085801 TUNING TECHNOLOGY FOR TRANSMITTERS.** Smart transmitters are a combination of good sensing and microprocessor technology. They offer the potential to make better measurements, to add options, such as internal square root signal conditioning, and also permit remote reranging, remote diagnostics and bidirectional digital communication. The development of the smart transmitter has been constrained by low power technology. Manufacturers have dealt with the power problem by selection of low power CMOS microprocessors and by reducing the clock speed of the digital circuits to hold the power down.

Gray, James (Foxboro Co). *Control Instrum* v 20 n 5 May 1988 p 103, 105.

**085802 IMPLEMENTING STATISTICAL PROCESS CONTROL: TWO CASE HISTORIES.** This paper describes a successful and an unsuccessful application of statistical process control techniques in manufacturing industry. The case histories show that the reasons for both success and failure lie with the senior management. The factors contributing to the successful implementation of the techniques and the benefits obtainable from using appropriate techniques are summarised. (Author abstract) 5 refs.

Sohal, A.S. (Univ of Bradford, Engl). *Qual Assur* v 14 n 2 Jun 1988 p 64-68.

**085803 HUMAN SIDE OF PROCESS CONTROL.** The Key Minimum-Maximum Standards Process Control System (KMS) promotes harmony by blending its many meanings in a way that motivates people and process control to respond to each other's basic needs for benefits

they share and also at a price they must share. The KMS system was originated to provide safeguards that prevent people and process control from maltreating each other when they work together. Managements that have best utilized the system have achieved excellent control and teamwork. An example concerns casting defects.

Smith, Kenneth M. *Mod Cast* v 78 n 6 Jun 1988 p 32-33.

**085804 NEW TOOLS PUT SPC IN HAND.** Many of America's top manufacturers will soon require statistical process control (SPC) and statistical quality control (SQC) data in a computerized and printed form from their suppliers. SPC/SQC reporting is an essential part of the more productive changes going on in inventory control (just-in-time delivery, particularly) and the trend towards closer relationships between manufacturers and their ever-smaller pools of suppliers. And the benefits, which will accrue mostly to the customers in the beginning, eventually will be felt by the job shops, screw-machine facilities and contract stamping plants that supply them. The statistical reports, such as X-bar and R charts, histograms, as well as sigma, and standard deviation are explained. An example is given where an SPC has been started in a small stamping plant.

Freyberg, Dale (MIT Corp, Paramus, NJ, USA). *Mod Mach Shop* v 60 n 12 May 1988 p 50-57.

**085805 SPC: A SEARCH FOR ZERO DEFECTS.** The basic theory behind the statistical process control (SPC) in particular the usefulness of the frequency distribution curve (the bell-shaped curve), is explained and exemplified by its application to the control of the manufacturer of 2-inch-long widgets. The successful SPC program introduced by the EIS Brake Parts, Middleton, Connecticut, is described.

Milton, Ray. *Mod Mach Shop* v 60 n 12 May 1988 p 60-67.

**085806 STARTUP OF A CATALYTIC REACTOR BY FUZZY CONTROLLER.** It is difficult to control the start-up of a packed-bed catalytic reactor with exothermic reaction by conventional controller. In this paper, a controller based on the fuzzy set theory is applied to such a system. The controller treats heuristic rules by fuzzy interpretation, and it is also equipped with adaptive scaling factors. The performance of the controller is experimentally examined with a reactor for the catalytic oxidation of hydrogen. (Author abstract). 7 Refs.

**085807 MOVE TOWARDS DISTRIBUTED CONTROL.** Changes in methods of controlling process plants take place slowly and therefore the trends which will be important in the market-place in the 1990s can already be discerned. The in-words will be microsensors, optical sensors, fibre-optics, digital communications, radio communication, bus architectures, distributed intelligence, distributed control, modelling, model building and expert systems because these are the in-words now in the universities and in the R&D departments. None of these advances can take place without standardisation of the communication methods and protocols. Users will insist that they retain the ability to mix and match transducers and control systems from different suppliers at least as easily as they can at present with a 4-20 mA standard.

Johnston, J.S. (Rosemount Ltd, Bognor Regis, Engl). *Meas Control* v 21 n 6 Jul-Aug 1988 p 175-176.

**085808 TOWARDS DIGITAL INFORMATION CONTROL.** The coming decade will see the end of the analogue era in process control. From the simple plant sensor to the terminal on the Managing Director's desk, the process control business will become completely digital. This trend will continue through the 1990s with digital components supplying economic solutions for signal processing and communication in all final field

devices such as sensors, valves and relays. The 1990s may well be characterised as the decade when 'Process control becomes fully based on digital information control'. Given these tools and technologies, users will increasingly apply them to operation of flexible plants and factories. In many applications, 'lights out' automatic operation may become common practice for overnight shifts.

Wood, G.G. (Foxboro Co, Redhill, Engl). *Meas Control* v 21 n 6 Jul-Aug 1988 p 179-180.

**085809 STATISTICAL PROCESS CONTROL: THE LESSONS TO BE LEARNED.** The authors, from their training and research activities, have identified a number of practicalities and pitfalls relating to the introduction and application of statistical process control (SPC) in the automotive supplier community. These include: senior management not taking their obligations for quality improvement seriously; insufficient thought being given to the role of the SPC facilitator; people who are not directly responsible for control of a process, collecting and plotting data on control charts; control charts being displayed away from the work area; an over-reliance being placed on SPC computerized packages; confusion over the type of control chart to use in a particular situation; a lack of action on the data collected and presented on control charts; and a lack of confidence to experiment with the use of SPC. This paper articulates these difficulties and speculates on the reasons for them. (Author abstract).

**085812 PAPERS FROM THE MARINE SCIENCES DIVISION: THE DAWN OF NEW TECHNOLOGY, PROCEEDINGS OF THE 1987 SPRING CONFERENCE AND EXHIBIT.** Proceedings incorporates 20 papers, of which one is presented in the form of an abstract only. The material is subdivided into six sessions that deal with: marine applications, communications, instrument design, special strategies for process control, retrofit of plant controls by microprocessor-based instruments as well as personal computers and programmable logic control-

lers (PLC) in process control. Topics considered include: computer hardware and software, versatile PC-based gaging system for remote tank management, compressor control, distributed control systems, petroleum refineries, chemical plants, data storage and compression, optimum controller tuning, multilayer microprocessors, use of logic in continuous process control, load shedding and management, enthalpy control of air washers in textile fibers, thermowell standardization, cost effectiveness of computerization, temperature sensors, and SCADA (Supervisory Control and Data Acquisition) systems. Technical and professional papers from this conference are indexed and abstracted with the conference code no. 10948 in the Ei Engineering Meetings (TM) database produced by Engineering Information, Inc.

**085813 CHEMICAL PROCESS CONTROL - CPCIII, PROCEEDINGS OF THE THIRD INTERNATIONAL CONFERENCE.** This volume contains 24 papers on the current state of process control. The papers focus on advances that have taken place over the last five years. In particular, developments in control system robustness, process operability, adaptive control, and model predictive control are highlighted. In addition new results on on-line identification and optimization, reactor control, and actual industrial applications of advanced control are presented. Lastly, the potential impact of artificial intelligence and expert systems is assessed. Technical and professional papers from this conference are indexed and abstracted with the conference code no. 11523 in the Ei Engineering Meeting (TM) database produced by Engineering Information, Inc.

## Alarm Systems

**085814 ALARM MESSAGES IN PROCESS CONTROL.** The process control industry is upgrading from hardwired alarm systems to computer generated alphanumeric messages displayed on CRT's. Unfortunately, the choice of message content, format and dynamics are typically left to the programmer. This article outlines work done on both alarm message content and format. Tests showed that more familiar portions of the message should appear in a 'postfix' position. Testing the dynamics requires situations close to reality. Thus, a series of low fidelity experiments is proposed that allows testing under reasonable circumstances. (Author abstract) ?

**Applications** See Also PAPER AND PULP MILLS—Machinery; WIRE PRODUCTS—Manufacture.

**085815 PROCESS INSTRUMENTATION AND CONTROL TODAY - DEVELOPMENT AND APPLICATIONS.** The turbulent development of large-scale integrated electronic components - LSI chips - in the form of microprocessors and memory chips has given a vital impulse to the formulation of new and more powerful automation structures. Improved microcomputers can now solve data processing problems which were previously only handled in large computer centers. This article takes stock of the state of process instrumentation and control (I&C) today, with some remarks about further developments in this field. An outline is given of some of the I&C applications. (Edited author abstract) 12 refs.

**Automation** See Also CEMENT PLANTS—Automation; COAL PREPARATION—Flotation; COMPUTER SOFTWARE—Process Control; CONTROL SYSTEMS, PROGRAMMED; DATABASE SYSTEMS—Management; ELECTRIC POWER PLANT EQUIPMENT—Construction.

**085816 DISTRIBUTED CONTROL SYSTEMS.** Distributed control systems for industrial automation have been available since the mid-1970s, and originally programmable electronics was used to realize the functions previously done with relays or hard-wired electronics. Newer systems use more efficient programming methods, and greater emphasis is laid on user friendliness and flexibility. A modern, integrated automation system combining instrumentation and PLC functions, as well as supervisory functions of the SCADA system is described.

Pauly, Thomas. *Electron Power* v 33 n 9 Sep 1987 p 573-576.

**085817 ARCHITECTURE FOR FACTORY CONTROL AUTOMATION.** The automation of manufacturing functions can be usefully categorized as physical, control, and information automation. Because control and information automation are functionally dedicated to processing data, they are founded in computing and data communications technology. But they characteristically differ in important ways, such as response-time requirements, variability of functionality, and volume and volatility of associated data. Thus, different computing architectures are appropriate for these automation arenas. This paper outlines the functional and performance requirements typical in control automation. It also suggests an architectural approach to the automation of factory control functions. (Author abstract)

**085818 PC GRAPHICS ARE KEY TO LOW COST AUTOMATION.** One of the areas in industry that is currently undergoing fastest change, potentially affecting everything from small scale process control, through the range of SCADA users, to piece part production, is computer graphics at (and beyond) the man-process interface. It is the graphics control systems that are now set to make one of the greatest impacts. This article will look at systems based on the IBM PC and its compatibles, aimed at providing: first, run time monitoring of intelligent instrumentation and programmable controllers; second, direct digital control via distributed I/O; and third, sophisticated off-line plant analyses.

**085820 EXPERT PROCESS PLANNING SYSTEM WITH SOLID MODEL INTERFACE.** This paper presents an integrated hierarchical framework of a process planning system with a Computer Aided Design (CAD) interface. The objective of the project is to integrate design with process planning using artificial intelligence (AI) techniques. The development of a CAD interface is discussed with respect to automated feature recognition, determination of tool approach direction, and deciding the precedence relationship between the features. Sample results from the CAD interface are presented. The expert system for the process planning module is discussed with the part representation and knowledge base, and the plan generation procedure. The module uses hierarchically organized frames for both part representation and the knowledge base. Some initial results are presented from the process planner to demonstrate the current capability of the system. (Edited author abstract) 40 refs.

## Computer Aided Engineering

**085821 CAE IN DER PROZESSLEITTECHNIK.** [CAE in Process Control Engineering]. The design and operation of chemical engineering plants involves collaboration of various specialist departments over a long period in an interactive sequence of steps. Any change in data in any of the necessary iterative steps can generate expensive errors. The aim of computer application and computerized development is thus basically to improve the integration of the various applications. Technical data processing, especially the use of CAD/CAE systems, therefore provides a framework for a whole group of measures intended to provide tools for medium-term automatic handling of data and re-use of partial solutions in memory. (Author abstract) 3 refs. In German.

**085825 CONTROL OF CONSTRAINED MULTIVARIABLE NONLINEAR PROCESS USING A TWO-PHASE APPROACH.** A computer-based algorithm is presented for the control of complex process units which are characterized by difficult features such as nonlinear input/output relationships, multivariable nature, operational constraints, imprecise models, and inadequate measurements. A two-phase algorithm is proposed to deal with these difficult features in a direct manner. The algorithm makes use of approximate process models which take into account significant physical and chemical events in the process. The first phase of this algorithm consists of identifying unmeasured disturbances and the parameters and states of the approximate model using measurements from the immediate past. (Edited author abstract) 15 refs.

**085828 PROCESSING PRODUCTION'S VITAL STATISTICS.** After a two-year examination of comparative statistical process control (SPC) systems, the quality engineers at Clayton Dewandre of Leeds opted to install the Precom system at their Hailwood & Ackroyd plant at Morley. The first of six networked SPC installations was initially for the small-valve product group; subsequently, it was extended throughout all manufacturing sections. Obtaining on-the-job feedback from all types of inspection and gauging functions appears to be a prerequisite for the successful implementation of statistical process control systems. The author probes the market for SPC-friendly gauging equipment.

**085830 STRATEGIES FOR BATCH CONTROL.** Batch master is a software utility that, hierarchically speaking, sits on top of the sequences. At its simplest level it can be realized by means of another sequence. The functions of a batch master are various but, essentially, it is in overall control of the sequencing operations. The four attributes of recipes which contain specific information and are used in conjunction with sequences during batch production are given. Sequential, parallel and common modes of batch operations are discussed.
